AMERICAN BEE JOURNAL.

ESTABLISHED IN 1861. OLDEST BEE-PAPER IN AMERICA.

DEVOTED EXCLUSIVELY TO THE INTERESTS OF HONEY-PRODUCERS.

39th YEAR.

CHICAGO, ILL., JANUARY 5, 1899.

No. 1.

CONTRIBUTED ARTICLES

Size of Frame to Use in Queen-Rearing.

BY G. M. DOOLITTLE.

A CORRESPONDENT says he is a reader of the American Bee Journal, and requests that I give my views in that journal regarding the size of frame that it is best to use when rearing queens. He wishes to rear queens next year, and is undecided whether to use the regular size frame for that purpose or make a smaller size especially for queen-rearing. And, as he wishes to make the preparations this winter, he is anxious that what I have to say will appear during the winter months, so it may be of use to him.

This may appear to be a matter of no general interest, but when it is fully understood that those who rear their own queens for general use in the apiary are the most successful honey-producers of the world, I think more interest will be taken in this part of our pursuit. There is scarcely an apiary in the land but what its owner realizes that he has in it one or two queens of more than ordinary value, but fails to breed for these valuable qualities because he does not understand queen-rearing; and so he lets the "goose which lays the golden egg" die without any special value to his stock accruing from her life, because he is not informed in the queen-rearing branch of apiculture. No person is an accomplished apiarist until he is a thorough master of the queen-rearing part of the business. With these few words regarding queen-rearing in general, I will now write regarding the size of frame which should be used, according to my ideas, based on nearly 30 years' experience.

During these years of trial as to which is the best size of frame to use in queen-rearing, I have failed to find any special advantage in a small frame, while, according to my views, there are many disadvantages; therefore, I have come to the conclusion that it is the part of wisdom to use the same size of frame in any nucleus hive that we are using in the hive which we have adopted for general use in the apiary. As we are used to handling these frames we can handle them more rapidly, and with less injury to the bees and combs than we can those of an odd size, thus saving time in our work, and avoiding that irritation to the bees which causes them to annoy their keeper by following him around and trying to sting him and everything else that happens near the hives.

With me it is much easier and more expeditious to handle one or two full-sized frames than three or four small ones. Then the bees work more to our profit where the regular size of frame is used. If any comb is built by the nuclei it is in just the frames we want it, and always of the size of cells we wish, as these small colonies build only worker-comb where the young queen is left long enough for them to build comb. Where I have had combs in which the

mice had gnawed holes, or the bees have made holes in them by cutting out moldy pollen, or in which there happens to be some drone-comb of more or less amount which I have removed, I always give them to these nuclei when forming them, and as soon as the young queen commences to lay, the bees will commence to build comb and repair these places, if honey is coming in from the fields, or if fed when no honey is to be obtained.

By leaving the young queen with them the length of time required, we have our combs all made as good as those built out on foundation, save the cost of foundation and the fuss of putting it in the frames, while such mutilated combs are just as good to form nuclei with as whole combs.

By a little looking over our combs each year, sorting out all those not being quite up to the standard, and using them as above, all the combs in the apiary can be kept in perfect

G. M. Doolittle.

order for all time, unless the cells should become so filled with cocoons as to become too small to rear bees in—a thing which has not happened in my apiary during the past 30 years.

Again, if we use the regular size of frames, all the honey stored in these will be right where it will be of use to us for any colony in the apiary, either for spring, summer or winter use, so that we do not have to store away a lot of

combs and honey at any time of the year because it is not in shape for use.

In connection with the regular size frame I would always use the regular size hive for nuclei. Why? Because in this way we have nothing which will be a loss to us, and by using the regular hive we are ready to unite for winter on any stand we desire, without changing hives or anything of the kind, or can build up any nucleus into a full colony at any time.

But, as I consider it, the greatest advantage in the full regular size hive comes in not having our nuclei robbed out occasionally, as is almost sure to happen with some of the weaker ones, where small hives are used. Such robbing causes a general demoralization of the whole apiary, often to such an extent that the bee-keeper almost wishes that he had never known such a thing as a bee. By using the regular size hive, and placing the nucleus on one side of it, while the entrance is at the other side, no nucleus large enough to hold a queen to advantage will ever be robbed out, and smaller than these should not be used.

To help the reader to understand better we will suppose that the regular hive is 14 inches wide inside, and that the entrance used is cut from the front board at the bottom, the whole length of it, and that the hive fronts south. Form your nucleus on the east side of the hive, using two combs, one of honey and one of brood; and next to these combs draw up the division-board or dummy, which should allow the bees to run under its bottom. Now close up all the entrance except one inch in length at the west side of the hive, and you will have it as I use them, and I have not had a single nucleus robbed since I found out this plan.

Now, suppose I wish a nucleus in the next hive on the same row in the apiary. In this hive I place the two frames and dummy next to the west side of the hive, while the entrance is on the east side, the conditions being the same as relating to the prevention of robbing, while the doorway to each hive is not at all similar. The next hive is fixt like the first, and the next like the second, and so on to the end of the row. In this way the young bees do not mix; and in returning from their wedding-flight no queens are lost by entering the wrong hive, as used to happen when I used an entrance in the same place with all the nuclei in the apiary. I consider this far preferable to painting the fronts of the hives containing nuclei, of different colors, or laying sticks of wood about the hives, etc., as has been recommended so many times in the past.

If the nucleus becomes stronger than is profitable on the two frames, move out the division-board and give them an empty frame with a starter of comb foundation, and see how quickly they will fill it with beautiful worker-comb. If too weak for the two combs, take away one and draw the division-board up so that it is suited to the wants of the little colony, thus always working to the best advantage, and making everything done by any or all count on the right side of the ledger page.

Onondaga Co., N. Y.

An Appeal for Co-operative Experimental Work in the Apiary for 1899.

BY R. C. MIRIN.

MOST apiarists do more or less experimental work. We might say that life, as it relates to our actions, is one long list of experiments. Experiment and research are necessary to advancement. He who is the most advanced is the man possessing the greatest aggregation of ideas.

To progress it is necessary that we think and experiment, and collective and extensive work carried on by many men and minds will progress more rapidly than if limited to narrow channels, both as to scope and to minds directing.

I am a natural investigator. The inheriting the inquisitive disposition, I did not inherit the filthy lucre to enable me to prosecute investigation to advantage, hence my efforts are, and always have been, very handicapped. The season I plan to work out certain lines of thought, often proves to be a very poor one for that line of work. Then, too, it takes several different kinds of seasons, and a great variety of conditions, to prove a theory.

Suppose we plan certain work for the coming season, and to carry out the experiments 10 or 20 apiarists in as many locations and under many and varied conditions, all join in the work, then compare notes—how great progress we might make in a single season! The same work in the hands of one man would be years in attaining the desired result—often would be abandoned in despair.

I am now going to appeal to the fraternity to assist me in some work for 1899. I will tell you some things I want demonstrated, how I propose doing it, and why. Others can no doubt help me in planning the details of the experiments, and can help in carrying them through. I do not want to name those who shall help, preferring to get volunteers. I do not know who can and will do the work, but you, reader, know for yourself and can offer your services. I think that a volunteer will do better work than a drafted man.

But you will want to know what we are to try to demonstrate, what theories we want to prove or disprove. I will name some of them:

PRODUCTION OF COMB HONEY VS. EXTRACTED.

It is said, and believed by many, that an apiary run for extracted honey, and with ready-made store-combs, will yield more surplus than will a similar apiary managed for section honey and having to build combs. The proportion of extracted over that of section honey is variously estimated at from one-fourth more all the way to three times as much. My own belief is, that where intelligent management is practiced, and in an average location, the surplus will not exceed the proportion of four to five in favor of the extracted.

I do admit that in basswood flows, or any flow that comes on *very abrupt and free*, honey may be lost where comb has to be built to receive it; but, while admitting this, I do think that to put out the unqualified statement that so very much larger yields can be obtained by running for extracted, and placing such before the average reader, is not doing the right thing. I am now nearing 25 years of quite extensive apicultural experience, and scarcely a year that I did not produce both comb and extracted honey, having very little basswood, buckwheat and clover, white clover, red clover, heart's-ease, Spanish-needle, alfalfa and sweet clover crops, and in all these years, and from the varied sources, and both summer and fall flows, never did I obtain twice as much extracted as of comb, per colony. Do you wonder that I want more positive support of the popular belief?

DIFFERENCE IN HONEY RESULTS BETWEEN COLONIES.

Another thing I want to see demonstrated, is the difference in work accomplished between a colony largely of young bees, and one whose bees are all of field-age. The reason for this experiment is to demonstrate the necessity of a good stock or supply of old bees in a colony to make it a good honey-gatherer. I believe that herein lies much of the difference in amount of surplus put up by one colony as against another that should *apparently* do equal work.

UNQUEENING DURING THE HONEY-FLOW.

A third experiment is to demonstrate the effect of removing a queen from the colony during the honey-flow. Many claim that a colony made queenless will not work with the vigor of one retaining the queen in full laying. It has been my practice for several years to unqueen about the beginning of the flow, and for several reasons. I have for nine years been running from three to five apiaries. All these years I never pretended to remain in the various yards to manipulate swarms, but visited each place as often as I could at intervals of one to three weeks. I have largely unquened to prevent swarming.

A second object was to have only sealed brood, or nearly so as possible during the main harvest, that the colony might give its whole attention to the work of gathering and storing. The advocates of natural swarming claim that the colony without a queen, even the one retaining its queen but not swarming, will not store equal to one allowed to swarm. Direct and comparative tests side by side, and date for date, are necessary to thoroughly demonstrate the matter and show it in a clear light.

OTHER IMPORTANT QUESTIONS.

Then there are the matters of big hives vs. little ones, big colonies vs. little ones, and a whole lot of unsettled matters. One question that is a factor in nearly all of the others, is the one of wax-secretion. We are taught, and the teaching has been generally accepted as correct, that for each pound of wax built into comb we have lost from 15 to 25 pounds of honey. Some put the loss of honey much higher than this.

It is argued that the production of wax costs directly the consumption of not less than 15 pounds of honey for one of wax produced; that the bees secreting this wax and building the comb, if not thus engaged would be in the fields after nectar; thus we have not only lost directly the 15 pounds of honey necessary to the secretion of the wax

(just as liberal feed is necessary when a cow is secreting milk), but in addition we lose in varying quantities what these same bees might have gathered from the fields if freed from secreting and working wax.

Contrary to all this, I believe that all normal colonies, when gathering nectar and ripening and storing the same, secrete more or less wax regardless of the need of it; and more, that the secretion and manipulation of this wax is principally by bees *under* field-age bees that would have been idle if not thus engaged. It seems to me that those who make claim to the doctrine of the great loss of honey when a colony has to build comb, make this assertion without due consideration of all the facts. Let me offer a few figures:

A 10-frame hive, Langstroth size, takes nearly two pounds of wax to construct its comb. Surplus honey from the same hive to the amount of 25 pounds, means about three pounds of wax secreted, which, at the ratio of 15 of honey to one of wax means 45 pounds of honey consumed in comb construction. Suppose that the loss by bees being detained from the fields that otherwise would have been there—say reducing the field-force one-third, amounts to one-third the total honey gathered. This would be reasonable surely. The brood-combs should contain not less than 35 pounds, which added to the 25 of surplus received would make 60 pounds. Thus the bees kept secreting wax and building it into comb, should have instead added to the total store another 20 pounds.

Put these figures together and what have we? Forty-five pounds of honey *consumed* in wax-secretion, 20 lost by bees kept at home—total 65 pounds. If such a theory is correct, a *swarm* hived and building *all* its comb and yielding a 25-pound surplus, should, if given all the comb they could use, have yielded, in addition to the 25 pounds, 65 more—a total of *90 pounds of surplus* honey. Is not this a reasonable conclusion?

My next will discuss details of experiments to prove the truth or fallacy of the general accepted theories.

Larimer Co., Colo.

Large Hives for Either Comb or Extracted Honey.

BY C. P. DADANT.

THE following letter, which was sent to the Editor of the American Bee Journal, is referred to me for reply:

EDITOR YORK: I think that many who are trying to solve the hive question will be misled by Mr. Dadant's articles on the proper size of hive. It should be remembered that Mr. Dadant is an extracted-honey man. I have looked in vain through his writings for his emphatic advice to use just as large a hive for comb-honey as for extracted.

I wish Mr. Dadant would answer this question: Do you advise just as large a hive for comb as you do for extracted honey?

Until I became a specialist, two years ago, I used the 10-frame Langstroth size, exclusively. After trying 8-frame and 10-frame hives in the same yard, I have come to the conclusion that I can get more comb-honey per brood-comb with the smaller hive, and have fewer unfinished sections.

I now think that those "who make their bread and butter by producing honey to spread upon the bread and butter or others," should figure their production as so much per comb, and not so much per queen.

After everything has been considered I think it will stand about this way: If you have nothing but the care of your bees to take up your time you will probably make more money with a small hive. If you have a farm to work, you would better use a larger hive.

Yours truly,

E. W. BROWN.

I would very much dislike to mislead any one, in whatever I write on bee-culture, but most especially on the hive-question, which, as is well known, we have tried to avoid, as it has been so often rehearsed and discussed that the subject has become stale to us. But it appears that, as others find that we succeed with a large hive, and hear that we prefer it to others, and have good reasons for so doing outside of our practical experience, they make inquiries about it, and this is why I have been requested to write a series of articles on the subject in Gleanings. So, if the subject proves worthless, and our experience proves injurious to the bee-keeping public, we will not feel as deserving of any blame.

I am very free to say that we are not at present comb-honey producers. All the comb honey that is produced in our apiaries is produced by our boys, for their own pleasure, on one, two or three hives, every season, and I notice that they take particular pains to select a very powerful colony in every case. But we *have been* comb-honey producers, and would be yet if we could get more than twice as much for comb honey as for extracted. But as long as we can sell extracted honey freely for three-fifths to two-thirds of the price we would get for comb, we will probably produce extracted honey.

The experience of Mr. Brown we notice to be similar to that of many others. They try a small hive—the 10-frame

hive—and finally change to something still smaller. We tried the 10-frame Langstroth hive with something still larger, and changed to the latter.

I have often noticed that the supporters of small hives agree that the large hive may be good for extracted honey, but is not suitable for comb honey; but I have never seen any one give a single reason for making this difference. The only attempt I have met to an explanation of the difference, is in an article by G. M. Doolittle, in Gleanings, in which Mr. Doolittle says:

"If the queen has all the vacant cell-room her prolificness requires, more room is only a damage to our crop of comb-honey, for in the finding of vacant cells in the brood-chamber, at the beginning of the honey harvest, comes an 'accustoming' to the brood-chamber for storing honey, instead of the sections, and thus the queen is crowded upon with honey, instead of said honey going into the sections," etc.

That is, if there is honey produced, with a large hive and not a very prolific queen, and there is plenty of room in the brood-chamber, this honey will be stored in the brood-chamber. This is just our experience, and when producing comb honey with large hives, we would do as some of the large producers of the East are doing, so I am told, who

C. P. Dadant.

have nothing to say publicly, tho they quietly work and produce tons and tons of honey, by simply reducing the number of combs, just at the opening of the crop, to the exact number that are covered by the brood, which just as efficiently forces the bees into the supers as if a very powerful colony had been placed in a small hive.

When we produced comb honey, let it be remembered, we were already using the large hives, and we did not practice the above-mentioned method, which I am told is so very successful with men like Elwood; and the result was, with us, that we always had too much honey in the brood-combs for winter, and we were in the habit of extracting it; but I wish to emphasize the fact, that, side by side with smaller hives, our colonies were, on the average, ahead of the others, just that quantity of honey which we were able to take from the brood-combs.

Now, please bear in mind that our experience was not based upon a hive or two, or upon one year or two, but that we have had as many as a hundred hives of one style, while we had two or three hundred of the other style, for years. It has always been a wonder to me, how comb-honey producers could do without an extractor, and this owing to the fact that, in large hives, we always had some that had more honey in the brood-combs than they needed for winter, when producing comb-honey. The Elwood plan would have done away with this, and would have forced the bees to put that honey in the supers, since the hive, in cases where the

queen lackt in prolificness would have been reduced or kept down to a size proportionate to the strength of the colony.

Now, please do not accuse us of saying that, with comb-honey production in large hives, you will have no swarms. We do not even say that, of our own methods, with extracted-honey production. But we do say, and we know every man who tries it will acknowledge, there will be less swarms, many of the colonies will be stronger, and the production of honey, on the average, considerably greater, since there will be a greater average production of bees in the hive.

Mr. Brown says: "If you have nothing but the care of your bees to take up your time, you will probably make more money with a small hive. If you have a farm to work, you would better use a large hive." But he does not tell us why. When some of our bee-men discuss the hive-question, they seem to take it for granted that the small-hive bee-keeper has all the colonies he can manage at the opening of spring, and that it is of little import whether all his queens have all the room they need. Mr. Hutchinson says, "Queens cost nothing." We can't take it from that point of view. Queens, tons in early spring, are the most expensive part of a colony, and we want each queen, in every one of our colonies in early spring, to have all the room she needs. If we have 80 colonies in one apiary, we want each one of those 80 queens to have the very best chance possible to display its powers, and we consider that the cost of the hive, which has to be replaced only about once in 30 years, is the smallest item of expense. The interest on the money-cost of a large hive, as compared with that of a small hive, is not to exceed 10 cents per year. This represents a necessary production of only about one or two pounds of honey more each year; and when we consider that a large hive may be made as small, by a division-board, as the smallest hives in the land, and can still, at a moment's notice, accommodate the very best colony in the country, with increase facilities for manipulation, we can but shrug our shoulders at the idea of any return to small hives, even if we desired to return to comb-honey production. Does this answer Mr. Brown's question?

Now, Mr. Editor, I sometimes think that it looks as if we had an ax to grind on large hives, but we have no patent, never did have, and don't care—no, not a copper cent—whether any one tries our methods or not. We know that it takes more of a bee-keeper to manage the large hives than the small ones, and therefore have no hesitancy in referring bee-keepers to the warning I gave some weeks ago, on trying new things, tho' ours is not a new thing, neither is it our own idea, but only a putting in practice of the ideas advanced by masters in the art long before us.

And as to the pride we might take in creating a larger following among the bee-keepers of the land, we are past that, too, for we have pupils and followers of whom we can well be proud, all over Europe and America, northern and southern.

Hancock Co., Ill.

No. 1.—The "Golden" Method of Producing Comb Honey Described.

BY E. A. GOLDEN.

I HAVE been requested by the Editor of the American Bee Journal to contribute a series of articles relative to my method of producing comb honey, for the benefit of its readers, with descriptions of the manipulations of my combination comb-honey hive, the idea of which I donated to the bee-fraternity of the world free and unstained from patent, altho' letter after letter has been received asking why I don't secure a patent on my hive, and make myself independently rich. My answer has invariably been, "No, no." For the reason that patented articles deprive thousands of poor bee-keepers from competing with their more wealthy competitors, providing the implement or method patented has superior advantages over the former. Realizing this fact in my own circumstances in life, I could do no better deed for my brother and sister bee-keepers than I have done in presenting the Golden method as previously stated, believing it to be far more profitable.

What I wish to say in regard to the Golden hive and method in this series of articles will be founded on practical experience, and not on theoretical knowledge.

As hundreds of new apiarists have engaged in our pursuit since my method was published in 1896, and are reading and hearing reports from bee-keepers who are working the Golden method with grand success, even realizing more than double the amount of surplus honey per colony than

from all other colonies by other methods, therefore, in presenting my method and hive before the readers of the American Bee Journal I shall do so honestly and truthfully. My object, then, will be to place before the bee-keepers of the world a system of producing comb honey which, in my judgment, will in time become the general method for the production of section comb honey.

But before doing so, permit me to insist that all who can will please re-read Mr. C. P. Dadant's wise letter of advice on page 675 (1898). It is chock-full of wisdom, and the result of many years of a practical life in apiculture. Then let us all revere Mr. Dadant for his words of advice, which will prove to be drops of gold to many bee-keepers if heeded.

In 1895-96 I was experimenting with the two-queen system, and by this method a tremendous force of workers or field-bees were reared and ready for storing nectar when the flow came, but being a close observer I soon discovered that such an army of workers could not freely enter the hive, having to crowd their way through in order to deposit their loads of nectar and pollen, and altho' the entrances were enlarged it did not seem to lessen the difficulty. It was then that I began to theorize upon the great improvements of Father Langstroth and others, and the thought suggested itself to my mind that men of long experience have from time to time been writing of different methods of the production of comb honey, and thus much valuable knowledge is gained by those who read the bee-papers and practice the valuable suggestions therein taught; however, there are thousands perhaps who yet claim, boastfully, that they know more than the bee-papers teach, and still persist in thumping the old tin pan and ringing the old preserved cow bells of a hundred years ago.

Thus, after due consideration, I conceived and put in practice two hives having side passage-ways from the bottom of the brood-chamber to the supers, having the outside made of glass, and as I was using the house-apiary my hives were rather crude. However, they answered the purpose, and the next day after the change was made, after spending an hour looking through the glass watching the thousands of little workers marching up the side entrances to deposit their loads of nectar, I noticed the entrance comparatively free and easy of access. I called to my good wife and assistant to come and behold a new and great discovery, that in time would supersede all other methods for the producing of comb honey, providing swarming could be controlled so as to keep the great army of workers in an unbroken compact.

Then the thought suggested was, Why not hive the swarm in what we termed "a double super," containing 48 sections? This was adopted, and success was the result. This method I have manipulated ever since, and have no desire for anything better, believing it the most simple and profitable method for the production of comb honey that I am acquainted with.

Morgan Co., Ohio.

[To be continued.]

CONVENTION PROCEEDINGS

UNITED STATES BEE-KEEPERS' UNION.

Report of the 29th Annual Convention, held at Omaha, Nebraska,
Sept. 13-15, 1898.

DR. A. B. MASON, Secretary.

SECOND DAY—EVENING SESSION.

[Continued from page 89.]

RELATIONS BETWEEN BEES AND ALFALFA.

Prof. Hunter, of Kansas, was then introduced to the convention, and in acknowledging the introduction he stated that he had been conducting some experiments within the past year upon the matter of the relations between the bee and alfalfa.

Dr. Miller: Won't you give us in a few words the result of your investigations concerning alfalfa?

Prof. Hunter: I was very much interested in what I saw in one of the Omaha papers of yesterday concerning some discussion that had been had before this convention regard-

ing sweet clover and alfalfa. I observed that there was a difference of opinion among you, but the reporter for the paper did not give any definite information as to what the sense of the association was. I have been working along this line somewhat, but there are men here who would naturally be better informed than I am as to the relative value of the two plants. The experiments that we have gone through with during the past year have shown that the value of alfalfa depends upon conditions—that in different circumstances there is a difference of results. Irrigated alfalfa does not give us the honey results that we get from alfalfa which has had a moderate degree of moisture from natural sources; and where it is on dry ground, entirely free from all humid influences, we get little or no nectar. I do not know whether that answers the question or not; but those are the three points that we have been working upon.

Dr. Mason—Are you sure you haven't made a mistake about that matter of irrigation and moisture in the air, and its effect upon the honey-yield?

Prof. Hunter—I am giving you the results of the experiments that have been conducted thus far.

Dr. Mason—Science sometimes makes great mistakes.

Prof. Hunter—I am always willing to grant that. One season's experiments would not allow me to give what might be called conclusive results. The theory that we have now is that irrigation simply affects the root of the plant, and its growth, while humidity of the atmosphere would more affect the blossoms. There is a certain percent of moisture taken from the atmosphere by the plant that would not be taken by the roots; that is, there are certain chemical changes that take place in the plant and in the flower, that we are not able to perfectly understand, but the theory is that the different conditions are produced by the different effects from irrigation and from rainfall. Irrigation does not give the humidity of the atmosphere that rainfall does.

Mr. Danzenbaker—Which is better?

Prof. Hunter—Rainfall gives better results.

Mr. Whitcomb—You were speaking in regard to alfalfa as compared with white clover.

Prof. Hunter—We have not much white clover where the alfalfa grows, so for the comparative results we shall have to depend largely upon the experience of the men who have dealt with both. The bee-keepers of western Kansas say it is equal—some go further and say it is better, but the conservative ones say it is equal to white clover in its honey. It would be very interesting to me to hear a little discussion among the members present upon that point.

Dr. Mason—I have often thought of what Mr. Root once had to say in *Gleanings*. Prof. Cook had made an analysis of Alsike clover, and found that it did not contain nearly the nutriment that other grasses do, and Mr. Root's idea was that he would give a great deal more for the opinion of the horses and cows on its food value than for the opinion of science. It may, or it may not, be true that what the Professor has said will work out all right in practice. If I understand him rightly, his theory is that alfalfa does not yield honey in a country where it is simply irrigated, and where there is no moisture in the atmosphere.

Prof. Hunter—I am trying to give you comparative results, or a statement of the circumstances where it would give you the best results.

Mr. Rauchfuss—I lived in the old country, in Germany, in a very moist section, where it rains nearly three times a week, and I never knew that alfalfa was a honey-plant while I was there—I never saw a bee on it, nor regarded it in the light of a honey-plant. When I came to Colorado I was surprised to see what quantities of honey the bees will sometimes gather from alfalfa, and I have tried to find out under what conditions the bees will do the best on alfalfa. For this purpose I have had two hives on scales. I have noted down the temperature, the maximum and minimum temperature each day, and also the general conditions of the weather, and I have found that in most cases a day that is fairly calm, with little wind, and comfortably warm, from 80 to 100 deg.—would be the best for the bees to gather honey from alfalfa. And in regard to alfalfa that is irrigated and alfalfa that is not irrigated, the latter the bees will visit, but they do not seem to get much from it. This year we have had about 20 acres of alfalfa within 500 yards of our bees. It was not irrigated on account of having too much other work, and the bees went right over that patch and visited some that was irrigated three miles off. We have had our bees go as far as four miles away into alfalfa fields that are in good bloom. Occasionally, of course, they will visit alfalfa that is not irrigated, but they do not do very much good on it. In regard to the maximum yield 10 pounds a day—that is, for a single day in the best of the season, has

been the most that we have ever had from one colony. Last year we had two colonies on scales, and one gained 101 pounds in 10 days. That was a fairly good yield. It was a good colony. The other colony that we had on the scales was not in nearly so good condition, but it discounted the other after all, for it stored 220 pounds of extracted honey in the season, while the one that made the 10 days' record produced only 180 pounds for the season. This last colony we have had on the scales for seven years, and during those seven years it has never had at any time in the season more than five frames of brood. It was in a 10-frame hive, and averaged about 200 pounds of honey a year. It was originally an Italian colony, but has been hybridized.

Dr. Miller—I would not give a blue button for the investigations of the scientist if they are not borne out by practical experience. But let us be very careful about underestimating the work of the scientist. We may find that there will be appearances of contradiction when there is no contradiction in fact. I very much doubt whether there is any real conflict here. The Professor tells us that the rainfall is worth more than the irrigating ditch, while on the other hand Mr. Rauchfuss tells us that the alfalfa that was irrigated was worth very much more than that which was not irrigated. There is not necessarily any contradiction here. The point is, the alfalfa in the one case was irrigated; did that in the other case have plenty of rainfall?

Mr. Rauchfuss—No, sir.

Prof. Hunter—Where there has been too much rainfall, you have another condition in which you get no yield. This year my work has been in 15 counties, but I would not like to have you understand that there is anything conclusive in the result of the experiments, because I do not consider that one season's work can be conclusive. We are beginning to work in earnest, and I am endeavoring to make every man who owns a colony of bees in the State of Kansas a co-operator in the work, whose testimony will be worth as much as mine.

Mr. Stilson—This goes along in the same lines upon which we have been experimenting in this State a little. To-morrow, when you are on the Exposition grounds, we will show you some results along these same lines of which the Professor speaks. You can get some profit by discussing the question out there.

Dr. Miller—Why is it that in Germany the alfalfa yields no honey, while it yields honey out here, and within 10 miles of my place in Illinois, it doesn't yield a drop?

Mr. Westcott—I have eight acres of alfalfa at my place that grew a length of nine feet this year. I let that alfalfa stand until it was in blossom, and in fact it was too ripe before I cut it. I never saw bees on it but one time, and then only a few. I visited it quite often. In the middle of the summer, before I cut it, I tried it again, but when I looked at it then there were no more bees upon it than there were in the spring. It is in blossom to-day, but I have received no honey from that alfalfa yet.

The convention then adjourned to hold an informal session on the grounds of the Trans-Mississippi and International Exposition, the next forenoon, at 9:30.

The following are the papers by Dr. Brown and Wm. McEvoy, previously referred to; the first is by Dr. Brown:

Needs of Bee-Culture in the South.

This subject embraces so much and presents so many topics for discussion that I am at a loss to know what to select for this short paper. You will find the needs in the South of the same character as the needs that are required for the successful and profitable culture of the honey-bee in all other sections of our country.

The first great need is an abundance of honey-producing flora; second, bees to gather it; third, sufficient knowledge on the part of the bee-keeper to enable him to know *when* and *how* to manipulate the bees in order to secure the most profit from their industry; and fourth, a market for the sale of the product when gathered. I think these are the great needs for profitable apiculture in any country.

In the South we have a greater variety of melliferous plants than there is in the North. The honey season is more extended, while the flow seldom comes in, as it were, in a rush. From the middle of June until the first of September bees seldom gather more than a support, except possibly along the coast of Florida, where the black mangrove grows. There is need of a forage-plant capable of standing drought and heat, and at the same time secreting honey, to come in and fill up this void between the close of the spring harvest and the fall honey-flow, which comes about the first

of September. For nearly 30 years I have been trying and experimenting, to find such a plant, but thus far I have failed to do so, and do not believe any such plant can be found.

The South needs to have more attention paid to the preservation of her native forest honey-producing trees; for instance, the poplar, which is one of the best. More attention should be paid to the culture and propagation of honey-producing plants, particularly to those having other uses than the mere secretion of honey. Crimson Alsike and white clover do well on most soils, but best on alluvial soil. The two latter clovers did well and secreted nectar abundantly

Dr. J. P. H. Brown.

in the latitude of Augusta, Ga., the past season. We need more attention paid to fruit-culture, for with it we get more sweets. We need to build up and preserve the honey-flora.

Knowledge of what to do, when to do, and how to do, is greatly needed. The person who invests money in bee-fixtures, and not in books of instruction, has just thrown his money away, for bee-keeping will only be a delusion to him. "Knowledge is power," and the mass of Southern bee-keepers need it.

With most honey-producers a better market is needed. Many look off to some big market, accompanied with big railroad freight and commissions, and lose sight of developing and building up the home market. By a liberal scattering of tracts explaining the properties and uses of honey, and offering it in small packages neatly and cleanly put up, a trade can be established in places where now only a few pounds are sold.

While the Lord helps all, the Southern bee-keepers need to put their shoulders to the wheel and work out their own salvation by pluck, knowledge and untiring energy.

J. P. H. Brown.

The following is the paper written by Mr. Wm. McEvoy, Foul Brood Inspector for the Province of Ontario, Canada:

Foul Brood Its Cause and Cure.

Foul brood will be almost a thing of the past when every bee-keeper keeps dead brood out of every colony of bees. The very filthy habit that so many have fallen into, of putting comb with dead brood in, into colonies for the bees to clean out, is a bad one, and one of the very best ways of spreading foul brood. Many a bee-keeper finding two or three of his colonies dead, and not knowing that they died of foul brood, has divided the combs among his best colonies, to get the bees to clean out the decayed brood he found in them, and instead of getting the combs cleaned out, spread the disease through his apiary at a rapid rate. I have always claimed, and do yet, that where brood-rearing is continued for a length of time in weak colonies, among a quantity of decaying brood, that it will sooner or later end in foul brood. If we want our colonies to keep in a healthy condition, and do well, we must keep dead brood out of them.

The young bee destroyed by foul brood first turns yellow; as it decays further it becomes a brown, ropy matter, and many of the capped cells (in bad cases) will be sunken a little in the capping, with a small hole in some of them. When the foul matter dries down it settles on the lower side and bottom of the cells, and sticks there like glue, and will remain there as long as the comb lasts. And when the bees are gathering honey they store it in the cells where the foul-broody matter dried down, just the same as they do in sound cells, and often seal them; then, as soon as the larva is fed any of the honey that has been stored in the diseased cells, it will die of foul brood; and when larva is fed in cells where foul matter dried down, it will also die of the disease.

No foul-broody colony in the world was ever cured, or ever can be cured, by the use of any drug. To cure an apiary of foul brood, every comb must be removed out of every diseased colony, and the bees thoroughly cleansed of the honey which they will take out of the old combs when they are being removed. In the honey season, when the bees are gathering honey freely, remove all the combs out of the diseased colonies *in the evening*, and shake the bees back into their own hives; then give them frames with foundation starters, and let them build comb for four days. The bees will make the starters into combs during the four days, and store the diseased honey in them which they took with them from the old combs.

Then in the evening of the fourth day remove the new combs and give the bees full sheets of foundation to work out, and then the cure will be complete.

By this method of treatment all diseased honey is removed from the bees before the full sheets are worked out.

All the old, foul-broody combs, and those made out of the starters during the four days, must be made into wax or burned.

The curing can be continued after the honey season closes, and the bees be cleansed of the diseased honey by feeding them sugar syrup *in the evenings* during the four days they are on the comb foundation starters, and when the little combs are removed, the fourth evening, and the full sheets of foundation given, the bees should be fed plenty of stores to winter them. Where the colonies are weak in bees, put two, three or more of them in one, so as to make good, strong colonies to start the curing with, and end the season with good, strong colonies, which are the only profitable ones to keep.

In all the thousands of diseased colonies that I have

Wm. McEvoy.

gotten cured of foul brood, I never had one empty hive boiled, scalded or disinfected in any way; and I know for a fact that the empty hives cannot give any colony the disease.

Wm. McEvoy.

DOCTOR'S ADVICE FREE. American Bee Journal subscribers (and especially the women of the households) are entitled to free medical advice on enclosure of a stamp to Dr. F. L. Peiro, Central Music Hall, Chicago, Ill.

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[Questions may be mailed to the Bee Journal, or to Dr. Miller direct.]

Introducing Queens.

Critic Taylor, in the Bee-Keepers' Review, calls attention to the fact (for which I thank him) that on page 727 (1898), in telling a sure way to introduce a queen, I did not mention that the queen should be put in. Come to think of it, it would be a good plan to put her in, but by no means at the time he suggests "not till a handful of bees appear." There would be nothing to gain and a good deal to lose by waiting so long. Put her in just as soon as you put in the frames of brood.

C. C. MILLER.

The Granulation of Honey.

There is a woman who sells strained honey here, and says it is pure, and of her own extracting, yet it candies quickly. Also a merchant here who has a lot of honey in pails labeled as *pure*, yet it is as solid as so much soft maple sugar. The directions say, "Put the pail in warm water and it will dissolve;" also that "all honeys will candy." Now is this true? Is it old or new honey? Or will new honey candy?

NEW YORK.

ANSWER. The exceptions are so few that it may be said that all pure honey granulates sooner or later, there being no exceptions that I ever knew in Northern honey. If you see a package of honey that has stood through the winter without granulating, you may be almost sure there's glucose in it. Cold weather hastens granulation, yet extracted honey generally granulates before freezing weather and sometimes before it is taken from the hive. If you get any extracted honey at this time of the year, you may feel pretty sure it will granulate soon after you get it, if not already granulated.

Queens Piping Board Cover Over Bees in Winter Prevention of Swarming.

1. Will you please describe, as nearly as you can, the sound of a queen piping? I do not know a thing about it, and I would like to know what it is like so I will be sure of what I am doing when the time comes.

2. On page 694 (1898), in the answer to the fourth question, from Michigan, I understand that you have used for some time a board cover instead of a quilt over the bees. Do you mean this for double-walled hives on the summer stands, with packing on top of the board cover? If so, how can the moisture go up through the board, as much of it ought to?

3. If I have the queen's wing clipped when she swarms, if I kill her and put her on the alighting-board, and the bees go in again, and when I hear the young queen piping, if I cut out all queen-cells will it be a sure plan to keep them from swarming?

BALDWIN.

ANSWERS. 1. That's a very hard thing to do. Sit down and try to write a description of the crowing of a rooster so that one who has never heard it will know exactly what it sounds like. But altho it's so hard for me to tell you what the piping of a queen sounds like, it isn't so hard for you to tell it when you hear it. The sound a queen makes when piping is a good deal like the repetition of the word "peep" or "teet." It's a rather shrill sound, uttered several times in succession, the first time long drawn out, then shorter and shorter, then the queen will be silent for a time considerably longer than she occupied in piping, when the piping will be repeated, perhaps in a different part of the hive, for when a queen is piping she generally is on the move pretty lively, only when she is piping she remains perfectly still. If a strong colony has sent forth a prime swarm, and nothing has been done to prevent the issue of a second swarm, you may hear piping a week after or later. Go to the hive in the evening after the bees have stopt flying and all is still. Put your ear against the side of the hive and listen patiently. Perhaps within two minutes you

will hear, "p-e-e-p, p-e-e-p, p-e-e-p, peep, peep, peep," and immediately after it you are likely to hear one or more of the young queens that are yet in their cells replying in a coarser tone, "quawk, quawk, quawk," the quawking queens seeming to be more in a hurry than the one that pipes. I don't believe you'll have much trouble to tell it when you hear it.

2. I use single-walled hives and winter them in the cellar.

3. Yes, if you cut out all queen-cells; but if you miss a single one it will not work. Neither is there any use of putting the dead queen on the alighting-board. The bees will usually come back without that, altho sometimes they may go into some other hive whether the queen is dead or alive. If you kill the queen, or take her away, do it when the prime swarm issues. If you leave her till the young queen pipes, the bees may annoy by swarming out several times before the young queen issues from her cell. By the time the young queen pipes, the old queen is likely to be put out of the way without any attention from you.

Staple-Spaced Frames Chaff Hives Pure Italian Bees vs. Hybrids T Supers vs. Pattern-Slats.

1. Do you consider staple-spaced frames all right to handle? In this locality regular Hoffmans are very badly stuck together.

2. Would you advise me to use chaff hives where there is no cellar to winter in?

3. Would it be best to buy pure-bred Italian queens, or breed from good hybrids? Each of two colonies of hybrids gave me over 50 pounds of nice comb honey from the fall flow of heart's-ease.

4. I am well pleased with T tins over pattern-slats. The bees enter more quickly, work better, and seal the outside sections almost as soon as the centers. I have destroyed all old pattern-slat supers.

ILLINOIS.

ANSWERS. 1. You will very likely like the staple-spaced frames much better than the Hoffmans, and perhaps you might like the right kind of wire nails still better than staples.

2. In your locality (central Illinois) it is doubtful whether it is advisable to use chaff hives. If you winter outdoors you can use single-walled hives with some protection.

3. Better breed from the pure stock. Suppose you reared a number of queens last summer from a pure Italian queen, and you found that these young queens had all met black drones, and that every colony of these hybrid bees stored 50 pounds of heart's-ease, while the pure stock did not do so well; it might seem to you that because the hybrids did the better work it would be better to breed from them. But if you did so you would probably find that the next generation of hybrids would fall behind the pure Italians. You'll probably get all the hybrids you want when trying to breed pure Italians, and you'll find those hybrids better than those that are reared from hybrids.

4. I am with you in preferring the T supers, but are you not giving them just a little too much credit? It hardly seems to me that there would be a very noticeable difference as to bees entering supers, and I can't see any reason why they should finish the outside sections in the T supers better than in the others.

Taking Bees from Between House-Partitions.

My friend in Long Island has a colony of bees that has made its home in the side of her house, between partitions, for several years. Once she took off the boards and cut out a large quantity of honey. She has become greatly interested in bees and bee-culture, and would like to have these bees, if possible, and wants to know when and how to do it.

HOLLIS.

ANSWER. Much depends on the "lay of the land," each case being a case by itself. However, having once cut out honey, it ought not to be a very hard matter to go just a step farther, cutting out the combs, and removing combs, bees, brood and all. Perhaps the best time to do this will be when fruit-trees are in bloom. Then put combs in frames after the manner described in your text-book as transferring. Some one who has had a little experience in handling bees ought to undertake the job, and he will know how to get the bees out of the way when transferring the combs.

BOARD OF DIRECTORS. E. K. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GEN'L. MANAGER AND TREASURER. Eugene Seecor, Forest City, Iowa.

VOL. 39. JANUARY 5, 1899. NO. 1.

NOTE.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England: "Change 'd' or 'ed' final to 't' when so pronounced, except when the 't' affects a preceding sound."

1899 is the way it is written now. Fast is the 20th century approaching. Another year, and the American Bee Journal will be in the last year of its fourth decade and second score of years. Forty years is quite a ripe age for a paper to attain unto, and particularly a *bee*-paper. It is rare that a periodical is older than its editor. But the American Bee Journal is such a rarity. But its age doesn't seem to weaken it much. It is not infirm if it is old. Of course, sometimes appearances are deceptive; but hardly, we hope, in this instance.

Dangerous Drugs as Cures for Bee-Stings are earnestly inveighed against by Somnambulist in the Progressive Bee-Keeper. "Never, never resort to the use of toxic drugs" for so small a thing as a bee-sting. Whiskey is sometimes recommended for bee-stings, but that is not so dangerous as drugs, for its character is known, while the others silently but surely fasten upon the victim without his knowledge until it is too late.

Bee-Chat is the name of a British bee-paper that has been published quarterly, but now comes out as a monthly. It is edited and published by one of England's best-known practical bee-keepers, S. Simmins, the author of that practical work, "A Modern Bee-Farm." Long life to the chatty Bee-Chat.

Shipping Beeswax.—We have handled quite a large quantity of beeswax during the past four or five years, and we have often wondered why so many ship it in heavy boxes

when sacks made of almost any material except paper are so much lighter and more easily handled. And then, there is no need of paying heavy freight or express charges on a clumsy box, weighing perhaps 10 pounds, and holding say 20 pounds of wax, when a sack not over a pound in weight would answer better in every way.

We once received several hundred pounds of beeswax from Utah, all in burlap sacks (the sacks weighing, we presume, about six pounds), when, had the shipment been put in heavy boxes, it would have weighed 50 to 100 pounds more. The freight charges on that lot of beeswax were about \$3 a hundred pounds. It would have been rather expensive to ship boxes at that rate, when the sacks were better in every way. But many do not think of these apparently little things which go far toward making the difference between success and failure.

A Roll of Honor is talk of by A. I. Root, composed of all who have taken Gleanings for 25 years, or since its first number, in 1873. That is a first-rate idea. We hope it will be a long roll. Suppose we, too, begin such a "roll," and compare it with Mr. Root's, just for fun, you know. Let us call for all who have taken the American Bee Journal for 25 years *or over*. Please mention the exact number of years, when writing us, and we will print a "Roll of Honor" sometime in February next month. Just drop us a card any time during this month, and let us see how near our "roll" comes to being as large as Mr. Root's.

How to Read a Bee-Paper is described by Mr. Harry S. Howe, of New York, in the last Bee-Keepers' Review. The plan he now wisely follows in reading is this:

1. Re-read the articles that seem of especial value.
2. Discuss them with any bee-keeper who gets in range.
3. Test a few of the best ideas on a small scale at first.
4. Lastly, read all the advertising matter in each paper.

Mr. Howe, the past season, read four of the bee-papers published in the United States, and said that when any two chanced to come together, he was like the boy who sat down between two pies—it didn't make much difference where he began.

The Spaniard is soon to become enlightened in bee-keeping, along with many other excellent things he is learning about, these days. Gleanings reports that the book, "Langstroth on the Honey-Bee," has been ordered translated into the Spanish language, by the Minister of Agriculture, of Mexico.

New York State's Honey Crop in 1889, according to the census of that year, was 4,281,964 pounds. Probably last year it was nearly 6,000,000 pounds, which shows that New York is a great State in more ways than in area and population. Take it year after year, it is probably the best honey State in the Union.

Sending Comb Honey to Market.—Since we have been trying to do something in the line of wholesale honey dealing, we have been getting some experience. We used to have very little sympathy with the honey commission firms, thinking that almost invariably the honey-producer was the much-abused man. Lately we have been thinking that some of them deserve being abused, especially some of the comb-honey shippers.

The trouble is, that every bee-keeper seems to think that nobody ever produced so fine honey as his—no matter if the combs are twisted around three ways in each section, and are all travel-stained and bulged besides.

Then, again, some do not seem to know the difference between white comb honey and amber—unless the amber is

a coal-black honey-dew. We have had a grocer reject a whole case, and refuse to buy at all, just because he happened to pull out a section of honey that was a trifle off color, when all the rest of the case was fine. That bee-keeper should learn not to mix his grades of honey, but keep them in separate cases, and mark them accordingly.

But what a pleasure it is to get in a lot of honey from a bee-keeper who *knows how* to assort and put up his comb honey for market. We have had at least two such lots this winter—one from Iowa and the other from Wisconsin. If we continue to sell honey to Chicago grocers, year after year, we will likely select the bee-keepers whose honey we desire to purchase.

We may say further, that we think less than ever of the commission method of handling honey. The buying-and-selling-outright method is the proper one, if the bee-keeper sends exactly the grade of honey he agrees to. If he misrepresents, he should have his honey shipped back to him, and be compelled to pay the freight charges both ways.

Low Prices for Honey, according to M. W. Shepherd in the American Bee-Keeper, are due to the fact that the laboring classes, the chief consumers of honey, get such low prices for labor that they cannot afford to buy honey. The remedy is to reduce the price of honey to compete with the cheaper sweets, and have supply dealers lower their prices. The editor says every one is at liberty to make his own supplies, and if any one thinks supply dealers make too heavy charges let him emphatically and forever disabuse his mind of that error by making his own supplies for one season. He concludes, "If the existence of our industry can be sustained only through a reduction in the price of supplies of the present standard of excellence, its days are numbered."

Bees n Switzerland. In an exchange we learn that Consul General DuBois says bee-culture has increased in Switzerland during the past 20 years 100 percent; that there are now 275,000 colonies in that country. The canton of Lucerne has 187 colonies to every 1,000 of the population, which is the highest average in Switzerland. This means a colony of bees for every family, or for every five or six persons in the canton of Lucerne. With its invigorating mountain air and delicious honey everywhere, Switzerland ought to be a healthy country.

MR. A. I. ROOT was 50 years old Dec. 9, 1898. May yet many happy, prosperous years be his.

THE NATIONAL FANCIERS' ASSOCIATION and Illinois State Poultry Association will hold their annual Poultry Show from Jan. 9 to 14, 1898, in Chicago. It promises to be a grand affair—and a great "cackling week" for this city. Everybody interested in poultry ought to attend this show.

MR. J. E. CRANE, a famous Vermont comb honey producer, visited the A. I. Root Company last month. He has about 500 colonies of bees, and produces as fine honey as we ever saw. We had the pleasure of examining about a car-load of his honey, and it was simply superb. But what surprises us is that he doesn't read the American Bee Journal. At least we can't find his name on our list. Just think what honey he might produce if he should take the Bee Journal!

MR. DOOLITTLE AND DR. MILLER are both referred to editorially in Gleanings for Dec. 15. The editor of that paper has visited these two leaders in American apiculture, and says that one (Doolittle) uses a meat-block on which to place his typewriting machine when using it, and the other (Dr. Miller) an ordinary high stool. Editor Root seems to have expected mahogany desks and upholstered chairs. Oh, no; busy, hard-working men like Doolittle and Miller have no use for "soft," showy and expensive luxuries. Only big bee-supply manufacturers can have such! Of course, all apiarian editors might enjoy them if they could afford to have them, but we know of only two, perhaps, that either possess such elegant things, or might if they wish. They are Root and Leahy. And we are not a bit jealous. We like to see other people enjoy themselves when they can afford it.

EDITOR HUTCHINSON, in the December number of his paper, says, "Success comes only with hard study, courage, thoroughness, and genuine enthusiasm." He ought to know, for we believe he possesses all of these characteristics, and, from his own words, has arrived at the coveted goal. It means a good deal to succeed now-a-days, especially when handicapped as some have been that we might name. But the race in life is not always to the swift or dashing; it is more often won by the patient plodder. We feel that it will not be ours to know whether we have won success—or successfully won; at least not for awhile yet. In the meantime we are content to plod on, ever striving simply to make a good, full-measure bee-paper.

HON. EUGENE SECOR, General Manager of the United States Bee-Keepers' Union, has been sick, hence the delay in mailing his annual report and voting-blanks. On account of his sickness, he has wisely taken the responsibility of changing the date of closing the polls from Jan. 1 to Jan. 15. We are glad to know that our General Manager is recovering from his illness, and trust he is quite himself again now.

MR. W. B. BLUME, of Cook Co., Ill., called a few days ago, and handed us \$1.00 for the Langstroth Monument Fund when renewing his subscription for 1899. Good way to do. Let others do likewise. Mr. Blume had his best crop the past season—3,500 pounds of comb honey from 80 colonies, spring count, and closing the season with 97 colonies, which he is now wintering.

MR. J. F. MCINTYRE, of Ventura Co., Calif., wrote us as follows:

"California bee-keepers are a 'blue' set just now. They have just past through the driest year since 1877, and are now threatened with another, and bees are not in condition to stand another dry year. Guess we will have to migrate if it doesn't rain this winter. How is Cuba?"

F. B. MILLS, of Rose Hill, N. Y., has one of the most beautiful 68-page catalogs we have seen. You will find Mr. Mills' advertisement in the Bee Journal during this month. Be sure to send to him for his catalog, and say you saw his name and address in the American Bee Journal. Then afterward buy some seeds of him.

THE CYPHERS INCUBATOR CO., of Wayland, N. Y., have a wonderfully fine catalog and guide to poultry-culture that they mail for 10 cents. Our readers will make no mistake if they send 10 cents for that catalog, and at the same time mention having seen the Cyphers Company's advertisement in the Bee Journal.

MR. E. E. HASTY, of Lucas Co., O., we learn, has terminated his long series of "A Condensed View of Current Bee-Writings" for the Bee-Keepers' Review. Mr. Hasty did fine work in that department. We presume the new "Department of Criticism" takes the place of the former by Mr. Hasty.

MR. E. J. CRONKLETON, of Harrison Co., Iowa, wrote us Nov. 11: "I have taken the American Bee Journal since October, 1884, and by its help and my own ability I have sold thousands of dollars worth of honey at a nice profit. No one should think of keeping bees without it."

Bad Year! the worst for 50 years! Most French bee-keepers haven't enough honey to winter their bees, says Le Rucher Belge.

An Australian Honey-Yield. W. J. reports in Australian Bee-Bulletin that from 80 colonies he got 11 tons of honey and increased to 115; $\frac{1}{2}$ 275 pounds per colony and 43 percent increase is not so bad.

Utah Yield. E. S. Lovesy reports in Gleanings the highest he has heard of in Utah the past season, as nearly 5 $\frac{1}{2}$ tons of honey from 31 colonies, increased to '82. That average 350 pounds per colony in an off year is not bad.

To Seal Bottles. Take four parts rosin, four parts pitch, and one part beeswax. Melt the wax, add the resins, and when the whole is liquid, dip the bottle in to the neck, take out and turn it around, holding the bottle horizontally, so all parts will be equally covered. Revue Eclectique.

To Keep Honey Light in Wax-Extractor. D. W. Heise (Canadian Bee Journal) is delighted at having learned that when cappings are put in the wax-extractor he can prevent the accompanying honey from becoming dark by never allowing the sun to strike the vessel containing the honey, and removing it just as soon as it has run down.

Plain Sections, says M. L. Main in American Bee-Keeper, are filled and completed more uniformly than others, and the honey in the outside rows will be more securely attached to the wood, hence a larger number will grade fancy. A picture of eight sections from his apiary shows the combs not so very well finished out to the wood.

Built-Out Combs vs. Foundation. Allen Sharp, in British Bee Journal, says that in his experience he finds that bees prefer fresh foundation in sections to unfinished combs of the previous season, or those that have been a long time on the hive. Some in this country agree with him, while others take the reverse view, saying that bees object to partly-built combs only when they are in bad condition.

Best Ventilation for Hives in Hot Climates, says W. W. Somerford in Gleanings, is that secured by raising the cover $\frac{1}{2}$ inch at one end, the flat cover being best. "If ventilated thus, hives with flat covers (even the covers are made of stuff only $\frac{1}{2}$ inch thick) will be perfectly safe to sit in any tropical sun, even when combs are full of honey in the top story." Of course such ventilation would not work well for comb honey.

Right Strain of Bees for Comb Honey, says J. B. Hall in the Canadian Bee Journal, must be great gatherers, not afraid to leave the brood-nest to store, filling the combs to the top-bar with brood, building combs without the use of brace-combs, filling the sections to the wood all around, and not afraid to cap it when full. Such bees can be kept, and are kept, but "it requires constant culling to keep out undesirable stock."

Salt-peter Rags for Smoker Fuel. I take a two-gallon crock of course larger or smaller would do, and throw into it a pound of salt-peter, then fill half full with water. Into this I put pieces of rotten wood or cotton rags. The wood must be allowed to soak for a day or so, but the rags may be taken out at once, or they may be left a month. If you use rotten wood for fuel, and wish to tell the salt-peter wood easily from the other, it's a good plan to throw a little red aniline dye into the crock. An old milk-pail with holes in the bottom, or an old colander, stands in the crock, and some of the rags are put into that to drain and dry. Next time I come for salt-peter rags I take them out of the colan-

der, put some out of the crock into the colander, and put some new ones into the crock. If none are dry enough I dry them in the sun or stove-oven. When I want to fire my smoker I take a rag, perhaps a piece of an old shirt or dress, the size of my hand (I don't mean the dress but the rag is the size of my hand), touch a lighted match to it, roll it into a little ball, and drop it into the smoker. Then, without waiting to see whether it will burn or not, I fill up the smoker with chips, planer-shavings, or what-not, with no fear but there will be a good fire with very little puffing.—Dr. C. C. Miller, in Gleanings.

Are Drones from a Drone-Layer Virile? Australian Yankee, in Australian Bee-Bulletin, thinks he has proved that they are. He had blacks, and there were no Italians within 20 miles. He got some Italian brood and reared late in the fall a queen that never produced a worker, but thousands of drones, worker-brood from other colonies being constantly added. Many of his young black queens produced progeny with yellow bands, showing that they had mated with the yellow drones from the drone-layer.

Uniting Colonies.—J. O. Gimsley, who conducts the "Department of Bees and Honey" in the Ruralist, is charmed with Doolittle's plan of uniting colonies. He varied from it by not caging the queen, and thinks it not necessary to cage her. To unite, he had two colonies with four combs each, 8-frame hives. He took queen from hive A, then put in A the combs, bees and all, from B, alternating the frames. No hive being left on the stand of B, the returning bees heard the call and joined the united colony, or else made their home with some near-by colony.

Which Way Should Combs in the Hive Run? G. M. Doolittle discusses the matter in Gleanings. In a state of nature bees build their combs in all directions. In this country most bee-keepers have the frames in the hive with one end toward the entrance. This allows the hive to be tipped forward so water can run out of the entrance. If frames hung crosswise, the combs would not hang true in the frames. There is better chance for ventilation in hot weather if frames run toward the entrance. Bees returning from the field can more readily get to any part of the brood-chamber.

Cleaning Hives Annually. F. L. Thompson says in the Progressive Bee-Keeper that for some years he has been inclined to think it time foiled away, laboriously to scrape all hives every spring; but he has swung completely around in his views since coming in charge of an apiary that had been run on the let-alone plan. It was such a terrible job to get all in good working order, that he will hereafter scrape clean each spring every hive. That gives chance for clipping queens and thoroughly inspecting everything at one opening early in the season; then in the swarming season he doesn't dread to open a hive on account of bur-combs, frames glued down, etc., but everything works easily and smoothly.

Doolittle's Box-Plan of Uniting a number of weak colonies is given in the American Bee-Keeper. For two or three small colonies make a box that will hold 12 quarts; for larger colonies, one that will hold at least 20 quarts. One side must be of wire-cloth nailed on. The other side should consist of wire-cloth nailed to a light frame, so it can be easily removed. A funnel is put in a hole in the top of the box. Blow a little smoke into the first hive, and pound on the top with the fist, then treat in like manner the others in succession. In five minutes from pounding the first hive, the bees will be filled with honey. Shake the bees into the funnel, caging the queen when found. A cloth in the funnel when not in use keeps the bees in. Bump the box down so as to shake the bees on the bottom, remove the funnel and cover the hole. Mix the bees thoroughly by shaking and tumbling the box. Bump it down again and drop into the hole a caged queen, having the cage suspended by a wire hook over the top of the outside of box. Have candy enough in the cage so bees will liberate the queen in four to six hours. Put box in cellar or other cool, dark place. Next morning if the bees were put in box in the evening, or in the evening if the bees were put in the box in the morning—take off the movable side and empty the bees like a swarm in front of their destined hive.

SEED DUE BILL FREE
 Forget new customers to test my seeds I will mail you handsome catalogue for 1899, lithographed and beautifully illustrated, and a 10c. Due Bill, good for 10c. worth of seeds for trial, absolutely free. It is full of bargains. All the Best Seeds, Beans, Peas, Potatoes, new Fruits, Furin Seeds, Potatoes, etc., at lowest prices. Ten Great Novelties offered without names. I will pay \$50. FOR A NAME for each. Don't buy your stock until you see this new catalogue. Several varieties shown in colors. Great inducements for orders this year. You will be surprised at my bargain offers. Send your address on Postal today. Tell your friends to send too. Old customers will receive a copy. F. B. MILLS, Seedsman, Box 88, Rose Hill, N.Y.
 Please mention Bee Journal when writing.

WONDERFUL DOGS how the Scotch Collie dog will learn to do your work for you, as well as protect your children and your home. Everybody pleased with ours and the prices. They are secured as fast as we can produce them. Write at once for particulars to POTTS BROS., box 10, Parkesburg, Pa. Ct. Please mention the American Bee Journal.

JUST AS NATURAL as a possible non-tradable. Doesn't betray off the nest and allow the eggs to chill but hatches every egg that can be hatched. **THE PETALUMA INCUBATOR** is absolutely perfect as to incubator essentials—proper attention and distribution of heat and moisture, regulation and ventilation. For 50 to 500 eggs. WE PAY FREIGHT ANYWHERE in the U. S. Handsome catalog free. Petaluma Incubator Co., Box 91, Petaluma, Cal.

The Rural Californian

Tells all about Bees in California. The yields and Price of Honey; the Pasturage and Nectar-Producing Plants; the Bee-Ranches and how they are conducted. In fact the entire field is fully covered by an expert bee-man. Besides this the paper also tells you all about California Agriculture and Horticulture. \$1.00 per year; 6 months, 50 cents. Sample copies, 10 cents.

In the multitude of counsellors there is safety. Prov. 11 14.

Best Size of Hive for Beginners.

Query 87. In the light of your own experience, what hive, or size of hive, do you consider best for a beginner to start with—1st, for comb honey production; 2nd, for extracted honey? OBITO.

- Dr. A. B. Mason 1 A 10-frame Langstroth.
- E. France 1 and 2. The Langstroth hive for both.
- R. L. Taylor 1. The 8-frame Langstroth hive. 2. Ditto.
- Prof. A. J. Cook 1 and 2. Langstroth for either or both.
- Emerson T. Abbott 1 and 2. An 8-frame "St. Joe," of course.

W. G. Larrabee 1 and 2. 10-frame Langstroth in both instances.

Dr. J. P. H. Brown 1 A 9 or 10 frame hive, with a frame the size of the Langstroth.

P. H. Elwood 1. Not over 2,000 cubic inches. 2. For extracting, one quite a little larger can be used.

G. M. Doolittle 1 and 2. The Langstroth frame is as good as any, and for a beginner 10 frames to the hive will be no mistake.

Jas. A. Stone 1 and 2. I have no other than the 10-frame "Improved Langstroth-Simplicity," because I like it best for all purposes.

Engene Secor 1 and 2. Localities may differ. For my locality and method of wintering, an 8-frame Langstroth seems to be as good as any.

Chas. Dadant & Son 1 and 2. We use larger hives than common, but if you take a standard, don't use anything smaller than a 10-frame Langstroth.

D. W. Heise 1 and 2. A Dadant-Quimby, if you should remain a beginner only. Apart from that, you must study your locality and be governed accordingly as to size.

J. E. Pond 1 and 2. Twenty-five years' experience causes me to advise the regular Simplicity 10-frame hive. I don't think a better one exists, and fully believe that others by its use will think as I do.

Mrs. L. Harrison 1 and 2. As far as my experience goes, a Langstroth hive for both. Localities may differ. I've had the best results with an 8-frame Langstroth, which can be used two-story for extracted honey.

C. H. Dibbern 1 and 2. One naturally loves his own child the best, and I think there is no hive equal for either comb or extracted honey to the "Dibbern." However, I believe a beginner will succeed as well with the Langstroth as any other.

R. C. Aikin 1 and 2. As circumstances may cause a change from one to the other, or a mixt production, your hive must suit either. I want a shallow frame, and to use from one to any number of sets as needed for results.

95% HATCHES

are often reported by those who use a **SUCCESSFUL INCUBATOR**

The reason for this record is absolute uniformity of temperature in egg chamber. Correct instructions for operating, has fire-proof lamp. Will hatch every egg that can be hatched. Send for new 118-page catalogue. Filled with hen information and plans of poultry houses.

Eastern Bee-Keepers!

Seven years ago we started an Apian Supply business in NEW YORK CITY, as we saw an opening here. That we made no mistake in this is shown by the large demand for supplies and our constantly increasing trade. Our aim was to furnish supplies promptly. In many cases bee-keepers find the freight on supplies from the Western factories is as much as the cost of the goods. In buying near home you not only save freight, but get your goods much more promptly. We keep several carloads of

Hives, Sections, Foundation, Etc.,

always in stock ready to ship, and the prices will be found RIGHT. We also run two apiaries for honey and sell BEES AND QUEENS. If you expect to use anything in the Apian line the coming year, you will do well to send for our catalogue. We would be pleased to quote you SPECIAL PRICES on what you want, as this is our dull season, and we can afford to sell for small profits. Hives, Sections, etc., are made in Wisconsin, where lumber is low, and the best can be had.

Our Special Price on Foundation, Hives and Sections will make you Smile.

Write for it, stating the quantity you can use. DEALERS should write for our 50 discount sheet which is now ready to mail.

HONEY * FOR * SALE.

Best White Alfalfa Extracted...

IN 60-POUND TIN CANS.

This is the famous white extracted honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can hardly get enough of the Alfalfa extracted.

Prices are as Follows:

A sample by mail, 8 cents in stamps, to pay for package and postage. By freight—One 60-pound can, 8 cents per pound; 2 cans, 7 1/4 cents per pound; 4 or more cans, 7 1/4 cents per pound. Cash must accompany each order.

Best Basswood Honey in Barrels.

We have a quantity of finest basswood honey in barrels, weighing 625 pounds net, which we are ready to ship f. o. b. Chicago, at 7 1/2 cents a pound. Sample mailed for 8 cents. If desiring to purchase, let us know, and we will write you the exact number of pounds in the barrel or barrels, and hold same till you can send the cash for it by return mail.

Our honey is ABSOLUTELY PURE BEES' HONEY, the finest of the kinds produced in this country.

We would suggest that those bee-keepers who did not produce any honey for their home demand the past season, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

Address,

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.

and always with a honey-board, and surely queen-excluding when extracting. Start with what you expect to continue with. Think hard and long, and get advice of skilled apiarists before starting.

Dr. C. C. Miller 1 and 2. That depends. If you intend to give the bees little attention, perhaps the Dadant or Quinby hive. If you intend to give all the intelligent care possible, the 8-frame Langstroth or dovetail, using as many stories as needed.

J. A. Green 1 and 2. Standard goods are best for a beginner, as a general rule. A hive holding 8 Langstroth frames would be about right for comb honey. For extracted I would prefer 10. The larger hive would be a better all-purpose hive for a beginner.

S. T. Pettit 1 and 2. 15 1/2 inches from front to rear, 17 1/8 from side to side, inside measure; and 9 1/4 inches deep, with 12 frames. The advantages are: Long entrances; more ventilation; wide hive, more super room; the section supers project front and rear.

J. M. Hambaugh 1. Much depends. For comb honey, 10-frame Langstroth for brood-chamber, Miller supers for surplus. 2. For extracting, the body above to be the same as the brood-chamber, here in California. I prefer the Dadant hive where wintering is a problem.

O. O. Poppleton 1. Let comb-honey producers answer this. 2. I can do better with a long single-story hive, with deep frames. For some reasons a more standard double-story hive would be best; but I couldn't conscientiously advise something I have myself discarded.

Rev. M. Mahin 1 and 2. The main thing in a hive is ease and facility of manipulation. As to size, something depends much in fact upon the honey-resources of the locality, and no universal rule can be given. I would make no difference between a hive for comb honey and one for extracted.

E. S. Lovesy 1. I prefer the 10-frame Langstroth, 28 sections to the super, with double section-holders, which virtually protects the sections. 2. The 10-frame short Langstroth we run three stories. It is easy to manipulate, and not so liable to break the combs in extracting.

G. W. Demaree I would have but one kind of hive (brood-chamber) for producing comb and honey in the extracted form. In the Southern and Middle States the standard Langstroth

10-frame is as good as the best I have tried. Further north, perhaps, the 8-frame Langstroth suits a shorter season.

Plain Section and Fence Endorst.

This year we had our first experience with plain sections and fence separators, and were very much pleased with the result. With the open sections it usually occurs that the inside sections of the super were filled first, but with the plain it was not so with us this year. In some cases the outer sections were the only ones in the

26c Cash Paid for Beeswax.

This is a good time to send in your Beeswax. We are paying **26 cents a pound — CASH** — upon its receipt. Now, if you want the money **PROMPTLY**, send us your Beeswax. Impure wax not taken at any price. Address as follows, very plainly,

The Bee-Keeper's Guide

This 15th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to give away to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without "THE BEE-KEEPER'S GUIDE."

Given For 2 New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two new subscribers—supply the Bee Journal for one year:

Send us Two New Subscribers to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both together for only \$1.75. But surely anybody can get only 2 new subscribers to the Bee Journal for a year, and thus get the book as a premium. Let everybody try for it! Will you have one?

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.

MARSHFIELD, WISCONSIN.

case that were filled, and the outside just as well finish as the inside. We had a separator outside of the last row of sections—before we put in the spacing board—and thought that was why they filled so well to the outside. Even tho some of the cases had but few sections of honey in them, they were filled out to the wood better than we ever had the open sections filled.

And as to the trouble with the plain sections shipping well, there is no question but that they are far ahead of the others, for the reason that the honey is so firmly united to the wood that it would be a hard matter to break it; and the face of the honey, we have seen no instance in which it protruded even with the wood.

Another thing, they are so easily cleaned.
JAS. A. STONE & SON,
Sangamon Co., Ill., Dec. 5.

Bees Did Nicely.

My bees did nicely during last summer. I have 15 colonies now, and they went into winter quarters with plenty of stores, so if none of them die during the long winter, through some unforeseen cause, I will have a splendid start next spring.

I am very fond of the American Bee Journal, which comes regularly every week during the year. My wife also likes it very much.
ARNOLD GERLACH,
Shawano Co., Wis., Dec. 12.

A Poor Season.

The past season was poor here; I got 300 pounds of surplus honey from 22 colonies. A man 30 miles west got 1,500 pounds from 50 colonies; another near me got three pounds from 50 colonies.
C. E. MORRIS,
Carroll Co., Iowa, Dec. 12.

Bees Did Well.

I think my bees did well. I started last spring with 16 colonies, and now have 51, and got 800 pounds of section honey. The bees are all on the summer stands, well packed in chaff hives, with plenty of honey.
ROY H. MOORED,
Osceola Co., Mich., Dec. 7.

Not a Good Season.

The past season was not a very good one for honey in this locality, but my bees are in good condition for winter.
JOHN S. DOWDY,
Logan Co., Ill., Dec. 9.

A Three-Year-Old's Report.

The American Bee Journal is indispensable to me. It has proven a sure guide, with what little common-sense I could mix in with it. It is my only text-book; when I want to know anything concerning my bees, I take the last year's numbers, turn to the index, and soon find what I want to know.

I started in three years ago, a green-horn, with two colonies. The first year I got 50 pounds of comb honey from one colony; lost one queen in swarming, by two swarms settling together, consequently I did not get any honey from the queenless one. I increased to four colonies.

The next year (1897) was a total failure, and everybody had to feed for winter stores.

Last spring I started with 6 good swarms, got 300 pounds of comb honey in one-pound boxes, and 300 pounds of fine extracted, besides increasing to 15 good colonies, after doubling up for winter.

My bees are all pure Italian. I requeened all my own, and sold a few queens. My queens are all purely mated. From one colony I took 100 pounds of well-filled comb honey, and from another 150 pounds of fine extracted honey. The hives were so full of honey when preparing for winter, that I took out from one to two full frames, and will save them for spring use.

It was so dry the latter part of the past season that I did not have any fall flow. I sold my honey from house to house at

Page & Lyon Mfg. Co.

NEW LONDON, WIS.,

Operates two Sawmills that cut, annually, eight million feet of lumber, thus securing the best lumber at the lowest price for the manufacture of **Bee-Keepers' Supplies,**

They have also one of the **LARGEST FACTORIES** and the latest and most improved machinery for the manufacture of **Bee-Hives, Sections, &c.**, that there is in the State. The material is cut from patterns, by machinery, and is absolutely accurate. For Sections, the **clearest and whitest Basswood** is used, and they are polished on both sides. THE "NOVELTY" POCKET-KNIFE

Your Name on the Knife.—When ordering, be sure to say just what Name and Address you wish put on the Knife.

The NOVELTY KNIFE is indeed a novelty. The novelty lies in the handle. It is made of beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed an AMERICAN BEE JOURNAL reminder, and on the other side, name and residence of the Subscriber.

The material entering into this celebrated knife is of the very best quality; the blades are hand-ground out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring steel, and the finish of handle as described above. It will last a lifetime, with proper usage.

Why purchase the Novelty Knife? In case a good knife is lost, the chances are, the owner will never recover it; but if the Novelty is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the Novelties, your pocket-knife will serve as an identifier; and in case of death, your relatives will at once be apprised of the accident.

How appropriate this knife is for a Christmas, New Year or birthday present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, a lady to a gentleman, or vice versa, a son to a mother, a husband to a wife, a brother to a sister or a gentleman to a lady—the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid, for \$1.00, or give it as a Premium to the one sending us three new Subscribers to the BEE JOURNAL (with \$3.00), and we will also send to each new name a copy of the Premium Edition of the book "Bees and Honey." We club the Novelty Knife with the BEE JOURNAL for one year, both for \$1.90.

Any Name and Address Put on the Knife.

GEORGE W. YORK & CO., CHICAGO, ILLS.

15 cents a pound, for both extracted and comb. I have sold to quite a number that kept bees, but did not get a pound from them.

I had quite a little experience, for me, with one colony. It became hopelessly queenless about May 1; it was in an 8-frame hive, and very heavy. They commenced coming out of the hive until the ground would be almost covered, would run around, double up as if they had the colic, and die. I thought some disease had gotten hold of them. This was for a number of days. I then transferred them into a 10-frame hive, and it stopt entirely—no more dead bees. I concluded that being queenless they were killing one another off, because they were too thick. I had sent to Georgia for a couple of queens, and was waiting for them to arrive.

I bought an Italian queen a year ago in the fall; they did not seem to increase much through the summer. This fall, when preparing for winter, I found the queen, being clipped. There were only a few bees, and a large swarm of drones. This was about Nov. 1. I killed the queen, and gave them a queen-cell from a nucleus that I had sold the queen from a few days before, then doubled up the nucleus with them; they reared a nice queen. I don't know if she mated or not. They had two or three good flights with a peck of drones, or less.

W. H. BROOKS.

Snobomish Co., Wash., Dec. 5.

Bees Dying from Grape-Juice.

I do not know whether I will have any bees or not next spring. They are dying off very fast now. There was a good crop of grapes here, and the bees got a great deal of juice out of them; the "honey" they stored from the grape-juice is killing them. I am glad to see the Bee Journal is trying to help improve the English spelling, for the English language and the American liberty will spread from pole to pole.

JOHN CRAIG.

Macoupin Co., Ill., Dec. 12.

Fine Surplus of Golden-Rod Honey.

The American Bee Journal came to us on "probation" this season, but has proven so good that it has to enter now as a "full member."

Bees winter successfully on the summer stands with but little protection in this locality. They went into winter quarters this fall with a good supply of stores—mostly from golden-rod—of which they gave a fine surplus. Bees had a good flight Dec. 4, but the hives are now almost hidden with snow.

W. L. MCGHEE.

Jackson Co., Ohio, Dec. 6.

Bees in the Great American Desert.

In the spring of 1897, I had 7 colonies, increased to 16, and got 1,220 pounds of honey, about half extracted and half comb.

In the past season I increased these to 30 colonies. The spring being cold and wet we lost fruit-bloom, locust, and box-elder. The first flow we got was from alfalfa. I secured 1,415 pounds.

I winter my bees on the summer stands, packed in straw or wrapped with burlap or carpet, with chaff cushion. My bees are strong and healthy. I feed light colonies early in the fall, and stimulate by feeding in March and April.

I don't have to ask many questions, as I can refer to my file of Bee Journals, or to "A B C of Bee-Culture," and find just what I desire to know. If the beginners would take Dr. Miller's advice, and get a good text book, they could find what they desire to know in five minutes; whereas, they must wait a week or two before they can find out through the Bee Journal.

My neighbors' bees are troubled with foul brood. I have armed myself with Dr. Howard's treatise on the subject, so I may be ready when the pest makes its appearance in my apiary.

I am well satisfied with the bee-business,

and attribute my success to the American Bee Journal. It arrives every Friday. I take the rocker in the warm corner, and Mrs. H. smiles and says, "Your testament is weekly."

I have been interested in the discussion in regard to a pure food law, by the members of the Union. I am not a member of that honorable body, but I hope to be in 1899. This great State of Kansas needs a law of that kind. Adulterated food is sold in our city every day, and merchants tell me that the honey they have for sale is adulterated, but it goes off very slowly until my stock of honey is exhausted. I think that Kansas can do something this winter. I have talked with our representative, who is a merchant here, and he will gladly do anything in his power in the House this winter, to get a pure food law in Kansas.

If General Manager Secor, of the Union, will send a copy of the Bill required, or to be adopted, to some good, live bee-keeper, or to some representative who will look after it, and if every bee-keeper in Kansas goes to work—sees or writes to their representatives and senators—I believe that this will be one among the States honored with a pure food law in 1899. P. R. HOBBLE, Ford Co., Kans., Dec. 9.

Red Clover as a Honey-Plant.

My 26 colonies of bees, spring count, produced 913 pounds of extracted and about 125 pounds of comb honey in one-pound sections.

I don't take much stock in red clover as a honey-plant. My bees work more or less on it almost every year during hot and dry weather; but it does not produce as fine honey as white clover; when candied it is coarser grained, and has a water-soaked appearance. I wish my bees would let it alone, for we have plenty of white clover when the red is in bloom.

FRED BEEDLY.

Poweshiek Co., Iowa, Dec. 11.

A Young Bee-Keeper's Report.

Last summer was the first time I ever handled bees, and had a poor year to start. I am 16 years old, and tend to my father's bees; he has about 105 colonies. I got only about 500 pounds of extracted honey and 200 of comb this year. I think the failure was on account of wet weather.

I have spent my Saturdays this autumn covering my hives with steel roofing. I had only three swarms last summer, and they were all late ones and stored no honey. I have about 25 empty hives which I hope to get filled with strong swarms next spring.

I am going to see Mr. Dadant some day; it is only about eight miles from where I live. I know I will enjoy myself.

My father is going to sow some alfalfa next spring, to try it.

EDMUND WORTHEN.

Hancock Co., Ill., Dec. 11.

A Wintering Arrangement.

I have been a reader of the valuable Bee Journal for three years, and have been studying the best way to winter bees. I have a way of my own, different from any I have read about. I will give a description of it:

I take a dovetail super and fit in a 3/4-inch board the size of the super; fit in the rabbits at each end, nail a 1/4-inch strip across each end of the board, so that when it is turned over it will form a bee-space between the frames and super.

I then cut a hole in the middle of the board the size of a quart fruit-can; have the can four inches high, and punch the bottom of this can full of small holes. Now make a box five inches square, and four inches high, and fasten around this hole. In winter I put the can in the hole and fill part full of cotton around the can, so as to receive all the steam; the cotton will hold the damp if there is any. I fill the super with oats chaff, as I am using

the chaff bives, and put a glass over this box. I can feed early in spring. I take this box out and put a section of honey in it, flat down, and do not disturb the bees. I can see them any time. Then, if I choose, I pour feed on this section, and there is no danger of robber-bees.

My bees stored but little surplus this year. B. O. WILLIAMS, Marshall Co., Iowa, Dec. 7.

Pamphlets We Are Out Of.

We find that there has been such a large call for our premium pamphlets lately, that we have run entirely out of the following, for which we have been substituting others of equal value, trusting that it would be satisfactory to those interested:

- Muth's Practical Hints to Bee-Keepers.
- Preparation of Honey for the Market.
- Bee-Pasturage a Necessity.
- Hive I Use, by Doolittle.
- Silo and Silage.
- Green's Four Books.
- Rural Life.
- Bee-Keeping for Beginners, by Dr. Brown.

Convention Notices.

California.—The California State Bee-Keepers' Association will hold its annual convention at the Chamber of Commerce, in Los Angeles, Jan. 11 and 12, 1898. Sespe, Calif. J. F. MINTYRE, Sec.

New York.—The New York State Association of Bee-Keepers' Societies will hold their annual meeting at the Kirkwood Hotel, Geneva, N. Y., Jan. 11, 1899. All interested are invited. Bee-keepers' societies are especially invited to send delegates. There will be an exhibit of microscopic preparations of foul brood (*Bacillus alvei*), and discussions relating to foul brood legislation. Mr. E. R. Root will give an address on the subject of foul brood. Ithaca, N. Y. HARRY S. HOWE, Sec.

N. E. Ohio, W. N. Y., N. W. Pa.—The 15th annual convention of the N. E. Ohio, Western New York, and N. W. Pennsylvania Bee-Keepers' Association will be held in the City Hall, Cor. 13th and Buffalo Sts., Franklin, Pa., Jan. 11 and 12, 1899. The following is the larger part of the program:

- President's Annual Address—Geo. Spittler, of Pennsylvania.
- "Spring Management of Bees"—L. K. Edgett, of Pennsylvania.
- "Summer Management of Bees"—R. D. Reynolds, of Pennsylvania.
- "How can the Conditions of the Local Market be Improved?"—B. W. Peck, of Ohio.
- "The best means of Increasing the Local Honey-Resources"—H. S. Sutton, of Pennsylvania.
- "Profitable Use of Comb Foundation"—J. T. Nichols, of Pennsylvania.
- "Making our Association More Useful"—Geo. Spittler, of Pennsylvania.
- "Preparing Bees for Winter"—N. T. Phelps, of Ohio.
- "Experiences of the Past"—D. A. Dewey, of Pennsylvania.

NOTICE—It is hoped that all will make an effort to be at this convention, and take an active part in the discussions. Special rates of \$1.00 per day for those attending the convention have been secured at the United States Hotel, on Liberty Street.

Geo. SPITTLER, Pres., Mosierstown, Pa. Ed JOLLEY, Sec., Franklin, Pa.

Emerson T. Abbott, St. Joseph, Mo.

HONEY and BEESWAX

MARKET QUOTATIONS.

Chicago, Dec. 19.—Market is about as last quoted. Best white comb brings 13c, with off grades of white at 11@12c; amber, 9@10c. Some lots have come on the market and are being offered at prices that would be reduced if buyers could be found. Extracted steady at 6@7c for white and 5@6c for amber. Beeswax, 27c. R. A. BURNETT & Co.

Detroit, Dec. 8.—No change in supply of honey as to quality, but prices are somewhat lower than last quotations, viz: Fancy white, 13c; No. 1, 12@12½c; fancy dark and amber, 9@11c. Extracted, white, 6@7c; dark, 5@5½c. Beeswax, 25@26c. M. H. HUNT.

Columbus, O., Dec. 15.—Honey arriving freely. There is quite an accumulation, and concessions in prices are necessary to move stock. Following prices are nominal: Fancy white, 12½c; No. 1, 11½c; No. 2, 10c; amber, 9c; dark, 8c. COLUMBUS COM. AND STORAGE CO.

St. Louis, Sept. 9.—Fancy white comb, 12 to 12½c; A No. 1 white, 10 to 11c; No. 1 white, 9 to 10c; dark and partially filled from 5 to 8c. as to quality. Extracted in cases, No. 1 white, 6 to 6½c; No. 2, 5½c; amber, 5c; in barrels, No. 1 white, 5½c; amber, 4½ to 5c; dark, 4 to 4½c. Choice Beeswax, prime, 24c; choice, 24½c. At present there is a good demand for honey. WESTCOTT COM. CO.

Kansas City, Sept. 9.—Fancy white comb, 12@13c; No. 1, 11@12c; amber, 10@11c. Extracted, white, 5½@6c; amber, 5@5½c; dark, 4½@5c. Beeswax, 22@25c. The receipts of comb honey are larger. C. C. CLEMONS & Co.

Milwaukee, Oct. 18.—Fancy 1 pounds, 12½ to 13c; A No. 1, 12 to 12½c; No. 1, 11 to 12c; No. 2, 10 to 10½c; mixt. amber and dark, 8 to 9c. Extracted, white, in barrels, kegs and pails, 6½ to 7c; dark, 5 to 5½c. Beeswax, 26 to 27c.

This market is in good condition for the best grades of honey, either comb or extracted. The receipts of the new crop are very fair, and some of very nice quality. The demand has been and continues to be very good, and values are firm on fancy grades and straight, uniform packing. A. V. BISHOP & Co.

New York, Dec. 20.—The market is well supplied, especially with dark. Demand is but fair for white and dark and off grades are being neglected. We quote:

Fancy white, 12 to 13c; No. 1 white, 10 to 11c; amber, 9 to 10c; dark, 7 to 8c. Stocks of extracted of all kinds are light. White, 6½ to 7c; amber, 6c; dark, 5½ to 6c; Southern, in barrels, 60 to 65c a gallon. Beeswax dull at 26 to 27c. HILDRETH BROS. & SEIGELER.

Buffalo, Dec. 16.—Our market has become somewhat quiet since the holiday trade set in, and we consider 12 and 13c an extreme quotation for best one-pound combs now; with other grades ranging from 7 to 10 cents, according to inspection. Very little demand for extracted at from 4 to 6c. We advise the marketing of honey as readily as it can be judiciously sold. BATTERSON & CO.

San Francisco, Nov. 22.—White comb, 9½ to 10½c; amber, 7½ to 9c. Extracted, white, 7 to 7½c; light amber, 6½ to 6¾c. Beeswax, 24@27c.

Stocks in this center are light and must so continue through the balance of the season. Choice extracted is especially in limited supply and is being held at comparatively fancy figures. Comb is meeting with very fair trade, considering that it has to depend mainly on local custom for an outlet. Values for all descriptions tend in favor of selling interest.

Boston, Nov. 28.—Liberal receipts with but a light demand during the holidays. As a result stocks have accumulated somewhat, and prices show a lowering tendency, still we hope for a better demand with prices at present as follows:

Fancy white, 14c; A No. 1 white, 12½ to 13c; No. 1, 11 to 12c; light amber, 10c, with no call for dark. Extracted, fair demand, light supply: White, 7 to 7½c; light amber, 6½ to 7c; Southern, 5 to 6c. BLAKE, SCOTT & LEE.

Cleveland, Nov. 29.—Fancy white, 13@14c; No. 1 white, 12@13c; A No. 1 amber, 10@11c; No. 2 amber, 9@10c; buckwheat, 8c. Extracted, white, 7c; amber, 6c; buckwheat, 5c. A. B. WILLIAMS & Co.

Indianapolis, Oct. 3.—Fancy white comb honey, 12 to 12½c; No. 1, 10 to 11c. Demand fairly good. Tar-colored comb honey, 8 to 9c, with almost no demand. Clover and basswood extracted honey, 6½ to 7c. Beeswax, 25 to 27c. WALTER S. POWDER.

Order Early

There are indications that the demand for SUPPLIES will be very large this season, and everyone should order as early as possible. We have large facilities for manufacturing all kinds of

Bee-Keepers' Supplies,

And will serve our customers as quickly as possible.

CONTRIBUTED ARTICLES

Honey-Dew—Its Origin and Uses.

BY PROF. A. J. COOK.

ON page 581 (1898) occurs the following regarding the origin of honey-dew:

"Honey-dew, on the contrary, is a saccharine substance or sweet juice which at times, and under certain atmospheric conditions, exudes from the surface of the leaves of trees and plants."

This occurs, we are told, as an editorial in the British Bee Journal, from which it was copied. We all know what a reliable journal that is, and that its editor, Mr. Cowan—the very likely he never saw this article at all—is a justly recognized authority on all such subjects. Yet I greatly doubt if this assertion is true. I know that all the dictionaries give a similar definition. They all assert that honey-dew is a product of both insects and plants. Even the very correct, and scientifically accurate Century, copies in substance the old definition, which, however, is corrected in part in a note from "Science."

That this definition should gain a place in our dictionaries, and might even have come from a scientist of high repute and recognized ability and accuracy, is undoubtedly true.

It is no uncommon thing that aphides—the source of very much of the so-called honey-dew—are located on certain branches of a tree—may be the topmost limbs. Yet their honeyed secretion is scattered and falls to lower branches, which are very likely the only part of the tree which comes under the observation of the pedestrian naturalist. He notes the nectar, and carefully searches for insects, which, of course, unless he climbs the tree, he fails to find. He concludes, that this is a secretion—"exudation" from the leaves. He so states in a scientific journal of known repute, and his conclusion, tho' wrong, becomes a dictionary definition, to be copied for years. An error, once in the dictionary, is very difficult to overtake and correct.

I once rode under some willows in Sacramento county in the '60's, the lower branches of which were sticky with honey-dew. I was on horseback, and carefully sought in the thick foliage for the aphides which I supposed were the producers of the nectar. I failed to find them on branches accessible tho' I was on horseback and sought as far as I could from the horse's back. I concluded that the honey-dew was secreted by the willow leaves. I now have no doubt that if I had climbed the tree and examined all the branches I would have found plant-lice. I think this because I have often seen just such cases since.

Every summer since coming to California, in 1893, I have seen willow plant-lice located on a single limb, and

that often high up in the tree. I have often noticed the same thing in Michigan.

I have no doubt that most observing bee-keepers who read the American Bee Journal have frequently observed the same fact. We thus easily explain the origin of the dictionary definition. We likewise understand how difficult it is to correct any such error when once given circulation in what we all suppose to be only the repository of thoroughly authenticated facts.

I will now give my reasons for doubting the plant origin of honey-dew:

1. I have now carefully examined this secretion for years, whenever seen, and have always found either aphides—plant-lice; coccids—scab insects; other Hemipterous—bugs; or else larva of insects (these are reported to me) often working in scores, to be the source of this nectar. This gives strong presumption that such is always the source of honey-dew.

2. We have reason to believe, in the economy of Nature, that energy is never expended by plant or animal that does

A Single "Ideal" Super of Full Sections.

See Mr. Keeler's Article, page 19.

not in some way benefit by such outgo. We are easily able to see how the insects profit by the secretion of this nectar. They thus lure bees, ants, wasps, etc., to their immediate presence, and these in turn repel the birds which else would feed on and destroy the insects.

I once noticed an exhibit of this function in Michigan, so palpably displayed that to doubt it was impossible. The Lecanium tilia—a large bark-lice—was thick on a linden tree close beside my study window. In early spring the beautiful song-sparrow commenced to feed on the young

scale insects which thickly dotted the leaves. Suddenly the bees and other sweet-loving insects commenced to visit the same leaves for the honey-dew which dropt from the coccids, and the birds at once ceased to come. In a few days cold, or preferably nectar in other places, kept the bees and their companions from the place, and the birds again commenced their good work. This alternation of bird and bee visits occurred several times. Such observations make the value of the expensive secretion to the insects clearly evident.

On the other hand, the honey-dew always becomes foul with the black smut or fungus that attacks sweet substances on tree or bush. We can hardly doubt that it is a serious evil to the plants, and are unable to see any good that comes to the plant from it. I fully believe it is always harmful to vegetation, and I feel certain that plants do not originate it to their own hurt.

I referred above to certain acorn-infesting larva that secrete nectar. I have never seen them, but have often heard of such—principally from Missouri—so often that I think they may be more than a myth. Yet I am free to say that I should feel more certain if I actually saw them. I can see how oak-tree plant-lice, which are by no means rare, might lead to an erroneous conclusion.

Ergot—a fungus which attacks rye and other plants—is also said to secrete honey-dew. If this be true, then I feel sure that the sweet in some way benefits the fungus. If it does the fungus no good, then I believe it, too, has other origin.

I hope all readers of the American Bee Journal will closely observe this honey-dew, whenever they have opportunity, and see if insects are not always its source, and report their observations in these columns.

In California, where scale insects and aphids are so common, it is very easy to study the honey-dew, and the black, repulsive fungus, which our orchardists denominate "smut." The walnut tree, this season, has been infested generally with an aphid, and the honey-dew and smut have always attended it.

It is not to be inferred that this honey-dew is unwholesome. It is a secretion, and not an excretion. It has a similar origin to honey, and may be as delicious. Much Aphid honey-dew is deliciously wholesome, and the honey from it is superior. Most if not all of the coccid honey-dew on the other hand, is dark and of ill flavor, and its presence in honey, or as honey, is greatly injurious, and can never be sold for the table. I have sold it by the barrel for manufacturing. This was used to make cookies, and was said to be all right by the manufacturer. I explained all to him, yet he gave the ruling price.

Often this honey-dew is produced in exceeding quantities, and I have known it to crystallize on the plants, especially on pine and larch trees, so as to encrust them with white, and become very conspicuous.

Our conclusions, then, which we reach tentatively, are these: Honey-dew is always a secretion from insects. It is always wholesome, and often delicious. It may be produced in exceeding quantities, and become the source of much honey. In such cases, coccid honey-dew honey will often be rank and ill-flavored, and should be kept as much as possible by itself, and sold for other purpose than table use. Honey-dew is secreted by insects to serve them in attracting bees, etc., which shall repel the bird enemies of the nectar-secreting insects. Los Angeles Co., Calif.

Something About the Wintering of Bees.

BY C. DAVENPORT.

THE honey crop in this section the past season was lighter than that in 1897, but the quality of that I secured was much better, owing mostly to the absence of pollen or bee-bread in the sections, and this was largely due to precautions taken to avoid this serious source of loss that often occurs in this locality.

Mr. Herriek, of this State, made the remark in the American Bee Journal a short time ago, that there will be less bees in Minnesota next spring than there are now. I fully agree with him as to this, for I never cellared bees before in as poor condition as mine were this year. Their poor condition was owing partly to reasons or causes I do not understand, and in part to the fact that there was a drouth and consequent dearth of honey the latter part of the season, on account of which brood-rearing stopt earlier than I believe I ever knew it to do before. For this and other reasons colonies were, as a rule, weak. I doubled up a good many of mine, and have them in pretty fair condition.

The weather in November, up to the middle of the month, was so mild that bees were able to enjoy good flights at short intervals, but about the 20th, when mine as well as all others around here that I know of, were out yet, this section of the country was struck by a storm that the local papers say was the most severe ever known here for the time of year—it was 18 degrees below zero, with a most terrific wind. I was away from home at the time, on account of which my bees suffered much worse than they would if I had been at home, for the covers from many hives were blown off, others tipped over and off the bottom-board, and besides the intense cold the air was full of ice and flying snow, but no colonies perisht outright, altho with a few hives tipped over, both cover and bottom-board were off, and it should be understood that they were exposed in this way from some time in the night until late in the afternoon, when I arrived. For owing to an accident, the man left in charge was unable to attend to them.

The most severe cold had not occurred yet, but before this affair took place it would have been hardly possible for me to believe that bees could exist under such conditions as some of these did. The colonies in the hives disturbed, as was to be expected, suffered a severe loss in bees—in some cases a third or more of their number perisht. I was not surprised at this, but was surprised to find a large loss of bees in many colonies, the hives of which were not disturbed in any apparent way by the storm. In many there were from one-half to one and one-half quarts, loose measure, of dead bees on the bottom-boards and between the combs. Other colonies no stronger, and in some cases much weaker, in hives as near alike as machinery can make them, lost hardly half a dozen bees.

The only way I can account for the loss is that the bees that froze may not have been with the main cluster, but the condition of the weather for two or three days previous, and the fact that the storm increast in severity gradually, and the large amount of dead bees in some colonies I deem it improbable that this wholly, if in part, accounts for it. But if this storm had not visited this section, I believe there would still be a large loss of bees here the present winter and coming spring, but this is only my opinion, for there are very many things about our pursuit that I know but very little about, and this is one of them.

A few years ago, however, under conditions that I fear were somewhat like this year, many practical bee-keepers in this State, or the southern part at least, had a large winter and spring loss of bees, owing, I believe, to causes or reasons unknown, tho many believed it was on account of colonies going into winter quarters with too large a percent of old bees, owing to the fact that colonies did not that fall have as large a percent of old bees as in other years, when there was practically no winter or spring loss. I can but believe that this had little if anything to do with it. One thing in favor of bees this winter is, that in my immediate locality, at least, their winter food, if natural stores, consists mostly of good clover and basswood honey, and I do not believe that being exposed to severe cold before being put into winter quarters would necessarily, of itself, warrant an opinion as to poor wintering, for I have sometimes left bees out late until they had been exposed to a number of severe cold spells, then cellared them, and in some cases I was unable to see but what they came through the winter and spring in as good condition as the average of those carried in early.

As an instance, I remember a number of years ago, 10 colonies in an out-yard were left over from the last load hauled home, and I decided to let them stay there all winter, and take their chances. But a week or so after New Years the weather became so bitterly cold that I changed my mind, and they were brought home and put into a cellar. Only one of these colonies died that winter or spring, and they had been exposed in single-walled hives to nearly or quite 50 degrees below zero, and without a flight since some time in the latter part of November.

The best authorities tell us it is best to put bees in, if they are wintered in-doors, before severe cold weather occurs, and this is undoubtedly the very best of advice; still, as I have shown, they will sometimes, at least, winter well under adverse conditions.

Before closing, I will relate an instance of bees enduring severe cold after they were put out in the spring in poor condition.

The previous fall I put in about 100 colonies with stores largely composed of honey-dew. About the first of January most of these colonies were badly affected with diarrhea, or dysentery, known by the hives being badly spotted. Towards the latter part of February there was a warm spell,

and one day the temperature being up to about 60 degrees, as I expected to lose most of them any way, about half of them were put out and had a good flight, and if any who think bees never spot clothes had been around I think they would have changed their minds, for not only everything in the vicinity, but the vicinity itself was badly spotted.

Very soon afterward it turned cold, and the temperature went down to about 20 degrees below zero, with a strong wind from the north, to which these colonies were almost wholly exposed. But altho they were unable to fly again until, if I remember rightly, sometime in the latter part of March, a small majority of them survived. Of the 50 colonies left in, about two-thirds of them died, either inside or soon after they were removed from the cellar.

Southern Minnesota.

Prefers the Tall Sections—A Report.

BY THADDEUS H. KEELER.

I SEND a photograph of a case of aster honey just as it came from the hive. The sections are the Ideal, 3⁵/₈x5x1¹/₂ inches. The honey was apt as white as any clover or basswood I ever saw. I have fallen in love with the tall sections, and shall use no other than the Ideals.

The honey crop for this section has been the poorest I ever saw. I had a few over 100 colonies in the spring, and had only 8 or 9 prime swarms, and about 200 pounds of spring honey, gathered from clover with daisy or bull-eye honey mixt with it. It was apt yellow, and tasted about as good as a daisy smells. The fall crop was the best I ever had; some of my colonies filled two supers, the first coming from golden-rod, and finishing up on aster. The frost held off very late in this section.

The photograph shows one of two supers taken from one hive, being the last one put on the hive.

Why Italian Bees Store Better Honey than the Blacks.

BY A. B. BATES.

IN coming to the front and telling why Italian bees store better honey than other bees when all have access to, and all store from, the same sources of supply, as Mr. Evins requests, may not be easily done; nevertheless, it is so, all the same. "The taste of the pudding is the proof."

A great many facts exist without any knowledge of the causes that produced them.

A few years ago I had two colonies of blacks, located side by side, and, judging from observation, about equal in strength, or number of bees and energy. There was no difference observable in the working of the two colonies—one stored surplus honey and the other consumed the honey in store, and at the same time; if any difference, the one that stored the surplus honey contained the most brood to feed. Why was this so? An answer to this might result in an answer to the other. My opinion is, that the "reach" of a bee is a more important factor in the characteristic of a profitable bee than many of us are willing to believe.

It is presmable with me, however adverse in the minds or clearer lights in bee-culture, that where there is a meagre flow of nectar it lodges in the bottom of the blossom-cups, and while some colonies are as numerous in bees and are as industrious, they are unable to reach it, and, if conditions remained such any length of time would die of starvation, while colonies possessing longer reaches would be storing surplus.

Now with regard to the question, Honey is heavier than water, and as a natural consequence the richer of the saccharine substance would settle to the bottom, and while black bees during a copious honey-flow might store as much honey less the weight of the evaporation of water it contains, the Italian bee having a longer reach cleans out the cup of the blossom-cell to the bottom, giving us not only a richer and finer quality and flavor from the same bloom, but the honey requiring less ripening or evaporation of water; the same quantity when first stored would result, in weight and bulk when ripened, largely in favor of the Italians.

My observation is that the same size comb when first stored by the Italian is more dense, needs less ripening, and is therefore heavier than that of the black.

I placed a 3-frame nucleus of Italian bees, one spring,

on a stand by the side of a populous 8-frame black colony. The season was poor, and the result was the Italians increased to 18 frames (filling an 8-frame and a 10-frame hive), and gave me 83 pounds of honey; while the black colony did not store a pound of surplus.

The difference in the reaches of the two strains, in my opinion, was the cause of the difference of production, and is also the cause of the difference of the quality in favor of the Italians.

Honey as a Fat-Producer—Nuts to Crack.

BY DR. C. C. MILLER.

MR. C. WURSTER, page 782 (1898), wants me to tell about honey as a fat-producer. I don't know enough. I'm not a scientist; only a bee-keeper. Evidently Mr. Wurster has been looking into the subject, and if he has any new light, by all means let us have it.

My knowledge of nutrition from the standpoint of a physician was obtained a good many years ago, and in that time some things have been unlearned by the profession. I have always supposed that when the heat-producing elements were assimilated, and they were not needed for immediate use, they were stored as fat, providing everything was in normal condition. The theory that I must first lay

Dr. C. C. Miller.

up in my own body as fat, the fat of pork, before I can get any benefit from it as fuel, is something new to me. That only such elements as require extra preparation by the digestive organs can be laid up as fat is also new to me. Every farmer knows that corn is a good fattener. One would be inclined to suppose that the sugar contained in it and gotten out in the form of glucose ought still to be a good fattener. If all the honey and sugar one eats must be used up at once in producing heat, and none of it can be stored up as fat, isn't there danger sometimes of one being overheated when one has a big feast of honey? But if there's any new light, by all means let's have it.

A. W. Hart wants me to crack some nuts that he gives on page 782 (1898). I am left partly to guess at what he wants me to tell, and any answer I give must be largely a guess. If I could have seen both cases, possibly I might do a little better guessing.

In the first case, the smaller bee was probably an ordinary worker that entered the cell and was shut in there. It happens rather often that after a queen leaves a cell a worker enters, and the other bees, fasten on the lid of the cell as a practical joke on the bee inside—a fatal joke for

the prisoner. How that fully-matured dead-queen happened to be in the cell, I don't know.

I can't quite understand the description given of the second case, but at any rate it seems that something came out of a cell, and afterward no queen could be found. It is barely possible that by some means the queen disappeared and a worker took her place; and it is possible that the queen was so poor she could not readily be distinguished from a worker.

Improved Frame Top-Bar for Fastening the Foundation.

BY LEWIS E. THOMPSON.

NOW and then some follower of a fraternal pursuit makes a discovery which he believes to be of value, but either from lack of means or selfish motives does not obtain a patent for his ideas. I may say that the following invention is published for both of these reasons.

Feeling, with the majority of bee-keepers, the necessity of a more secure way of fastening foundation into brood-frames, my father, Irwin Thompson, set out to study up a better way than the uncertain methods of sticking the sheets into the frames, in grooves, or to the flat surface of the top-bar. The result was the best device he has seen or heard of—one that is practically secure.

A top-bar is made of the usual length, $7\frac{1}{2}$ inch wide and $\frac{1}{2}$ inch thick. It is then sawed lengthwise in the middle to within one inch of the end. Thus the top-bar is in two pieces all the way between the end pieces of the frame. In nailing the frames together the end of the bar that has not been sawed through is nailed on as usual. At the end where the bar is in two pieces, only one piece is nailed before the foundation sheet or starter is put in.

When the foundation is put in, the bar is spread open by pulling on the free end of the half of the bar which has not yet been completely fastened, until there is sufficient room all the way along the opening to the other end-bar to admit the foundation. (If the inch which was not sawed splits out no harm is done, for two nails have been put in at that end—one near each edge of the top-bar—and it is still fastened.)

When the foundation is in, the nailing of the other end of the bar is finished by putting a nail in that end of the loose prong, the foundation having been prest between the two halves of the top-bar as in a clamp. Nails are then put through the bar edgewise to further secure the foundation.

My father has a form in which to lay the frame while putting in the foundation. There is a board the size of a full sheet of foundation and about $\frac{3}{8}$ -inch thick nailed on another larger board. This is to support the foundation while it is being fastened in the frame. The frame is laid flat with the thin board just fitting the inside, and with other pieces outside of the bottom and end-bars to hold the frame solid while the nails are put in. Erie Co., Pa.

A Hive-Tool 10-Frame Hives—Queen-Cages.

BY J. A. BEARDEN.

DURING a year of universal failure, such as this has been so far as bee-keepers are concerned, anything of especial economical value should have first notice, so it seems to me. Still, the main subject seems to be, Who has invented the best hive-tool? Hence, I will describe my invention, which is a piece of steel $\frac{1}{2} \times 1$ inch, about 12 inches in length, with one end drawn out to about $\frac{1}{2} \times \frac{1}{2}$ inch, and sharpened sidewise like a screw driver, for moving frames. The other end is drawn out as wide and thin as possible with the end for the edge. But right here is where almost all of the hive-tools quit off. Mine is carried just a little farther, so this wide end is just turned at right angles to the main body or handle, and sidewise of the same, and then it is sharpened with the bevel all from the outside end, thus making a fine scraper for cleaning covers, hives, etc. Then the tool is relieved of all sharp corners on the handle, and rubbed generously with some emery cloth to smooth and polish, and you are all ready for work.

Of course this is not the best, but if any one can tell us an improvement let's have it, for the best is none too good.

The hive discussion has rather cooled down of late in the Bee Journal, still, the cooler times are close at hand with some snow here just a few days back. It was the

first snow I can recollect seeing in October, as I have always lived here in Lincoln Co., Tenn.

Still, the 10-frame hive beats the 8-frame in this county, and for this reason alone: When the fall flow of honey is taken, most bee-keepers take all the honey in the top stories or supers, thinking that the bees have enough for winter in the lower story, and of course the honey is all above. So the 8-frame hive, to accommodate a good-sized colony, must be three stories high, and when the top one is taken he says: "I'll bet that they have got plenty down below, for Mr. So-and-So always takes the honey out clean in all but the bottom story for winter."

But Mr. So-and-So has the 10-frame hive, of two stories, and the bees have filled out both sides of the brood-chamber with good, thick honey, that was carried above in the 8-frame hive. So if the bee-keeper is careless, or very busy, he would better get the 10-frame hive, but not with the Hoffman self-spacing frame, for goodness knows I don't need a frame that takes a quarter of an hour to remove from the hive; but I do want all of my frames, to have the thick top-bar. Also, it is a good plan when putting frames together to use some small wire brads for nailing the bottom corners of frames crosswise, as they will be three times as strong as if they had been nailed into the end of the end-bar from the bottom side.

I don't know, or understand, why the manufacturers of supplies use wire-cloth for making queen-cages, for the perforated tin used by tinners for making molasses skimmers is much better. It is not very costly, is smooth and stiff, with plenty of ventilation, and so much better to get in shape, and keep in shape; and the holes are just the right size for a $\frac{1}{4}$ -inch tack.

I don't want any more entrance-feeders, for they are good fuss-breeders, causing trouble where none would have happened if a feeder had been used on the hive-top, by getting the bees in the notion to rob one another.

Lincoln Co., Tenn., Oct. 30, 1898.

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, *Marengo, Ill.*

(Questions may be mailed to the Bee Journal, or to Dr. Miller direct.)

Dead Queen at Hive-Entrance Camphor-Balls for Mothworms.

1. What is the best plan to pursue when you find a dead queen, at this time of year, at the entrance of a hive that has been packed for winter on all sides except the front on the summer stand?

2. Can camphor-balls be used in any way to keep moth-millers out of hives, by putting them under the roof, or above the enameled-cloth or quilt? Or can they be used to kill the wax-worm which may be in some frames of honey placed in empty hives and set aside for next season, or in cases of section honey? NEW JERSEY.

ANSWERS. 1. Let it entirely alone. You can't do any good by meddling with it now, and will be pretty sure to do harm. Just as likely as not the colony has a good queen, for a dead queen in front of a hive doesn't always mean that the colony is queenless. When bees begin to fly well in spring will be time enough to look and see whether any brood-rearing is started. If not, it will then be time enough to decide whether it is best to break it up and unite with other colonies (and the probability is that will be the best thing if it is queenless) or to give it brood in case it is strong, so as to coax it along till you can give it a queen.

2. No, don't waste time and camphor trying it.

Clover Questions.

Which is the best clover for bees, sweet clover, Alsike, or some other? How much should be sown on an acre, and when? What kind of land is best, and which is the best kind of grain to sow it with? What kind of feed does it make for cattle? Is wet or dry land necessary? IOWA.

ANSWERS. Some of your questions hardly come within the scope of apiculture, but I can tell something about the

matter. For Iowa, probably sweet clover will yield more honey to the acre than any other clover. It is good for forage if your stock have learned to eat it. Some find the dry hay eaten more readily than the green clover. Some say they can't get their stock to eat it. It yields a large quantity of forage, and may be cut two or three times in a season. It yields honey after white clover has ceased yielding, and is valuable on that account. As an enricher of the soil it is excellent, and will grow on poor land or pure clay. Alsike is one of the finest for honey, coming about the same time as white clover. If you have plenty of white clover, it is not as valuable for you as sweet clover, but if white clover is scarce Alsike may be worth more to you, as there is no question about its value for hay or green feed. It is best on land not too dry. Sweet clover will stand wet or dry. Sow either one about the same as you would red clover, and with the same kind of grain, using a little less seed to the acre than you would where red clover is sown with no other grass seed.

Making a Straw Hive.

How is the old straw skep or straw bee-hive made? I always admired the shape, form and style of the straw bee-hive—that is, the illustrations of it, for I never saw a real one—and I should like to make or procure one, if one is to be had, just for novelty. MAINE.

ANSWER. I suppose a band or rope of straw is made, coiled about and sewed together till the hive is done. But I'm no authority on straw skeps, and will yield the floor to John Kline or some other veteran. By way of a side remark, I may say that it is doubtful if your admiration for the shape, form, and style of the straw skep will remain as great after seeing the genuine article. Some things look best in pictures.

Sowing Clover for Late Bee-Pasture.

I want to seed some ground for bee-pasture. What kind of clovers would be best to sow—those that could be sown in the spring and blossom in the fall so that the bees could work on them before cold weather? ILLINOIS.

ANSWER. Probably no other clover is so good for late nectar as sweet clover. But it will not blossom the same year it is sown. It blossoms the next year, then dies, root and branch. You can manage, however, to have it blooming on the same ground every year after the first year. Sow in the spring, and then sow again on the same ground in the fall or the next spring, and it will re-seed itself thereafter. By cutting it before it is budded for blossom, or just when it first shows buds, you can make the main yield come later, which is an advantage where you have a crop of white clover. Alsike may be made to bloom tolerably late by cutting early enough. Very likely you may find Alsike to suit you better for hay and pasture, unless your stock has been taught to eat sweet clover.

Section Honey Over Old Brood-Combs.

Would a good quality of comb honey be produced (without fishbone) by hiving a new swarm on old combs with full sheets of extra-thin foundation in sections?

I have two colonies and do not desire more. I will reduce each to four frames and unite when the queens have filled the combs with brood. I will have the honey extracted from eight frames, and, desire, if practical, to use the same as stated above. Of course, I would not care to jeopardize the quality of the product, and hence ask advice. Last season I used part of the sections with starters, and part with full sheets, and consider those with full sheets the nicest to look at. In answering, consider one season with another, and average, as I realize that results might vary under changing circumstances. CONNECTICUT.

ANSWER. I suppose the emphasis in your question lies on the old brood-combs and the full sheets in sections. Much the larger part of all the fancy honey that is produced is probably produced with old combs in the brood-chamber. I know that I have produced some such honey over brood-combs black with many year's use, and wouldn't think of displacing those old combs, altho there may be a little advantage in having brood-combs that are entirely new, especially if the sections should be left on too long. When left on long, a little of the darkness is likely to be carried

up to show on the cappings of the sections, but if taken off as soon as finish it is hardly likely that you would notice the difference between sections produced over old and new combs. There is some difference of opinion as to whether full sheets or starters should be used in sections. In my own practice I prefer the full sheets.

Sowing Sweet Clover and Alsike.

When is the time to sow sweet clover seed? How much to the acre? How do you prepare the ground? Also, how and when is Alsike clover seed sown? INDIANA.

ANSWER. Sweet clover may be sown any time after the seed ripens in the fall till late the next spring. Perhaps the very best way to make sure of a good stand is to sow on hard ground and let it be thoroughly tramped in the ground when the ground is wet. That's the way it's sown on the roadside, and it seems to flourish nowhere better. You may also sow in cultivated ground the same as red clover, only if sown shallow in mellow soil it is likely to heave badly in the winter. If covered rather deep, or if the ground is rolled down pretty hard, heaving will be avoided. Sow Alsike the same as red clover, only half as much seed will do.

Preparing and Shipping Bees.

1. Can bees be shipt in less than car lots?
2. Tell me just how you would prepare bees to be shipt from Texas to Wyoming.
3. When would you ship the bees? TEXAS.

ANSWERS. 1. In some parts of the country they can be shipt as freight only in car lots. Your station agent will tell you how it is on your road. Of course, a single colony can always go by express.

2. If only a small number, each one should have wire-cloth covering entire top of the hive, and raised several inches above the frames. In any case there should be some plan to provide plenty of air, depending somewhat on the kind of hive as to preparation.

3. Not till the weather has become warm enough so the combs will not break easily. In freezing weather they are brittle and will break with very little provocation.

Sawdust in Double-Walled Hives.

Will sawdust put between the walls of a hive be as good as chaff? SUBSCRIBER.

ANSWER.—Sawdust is not generally liked as well as chaff. If you use sawdust, be sure to have it very dry. If you get sawdust at a planing-mill, you can also get planer-shavings, which are well liked for packing.

A Colony Feeding Caged Queens.

Can a queenless colony of bees be depended upon to feed the queens kept in West cages, or is it necessary to put feed in the cages? TENN.

ANSWER. I think it will not be necessary to put feed in any cage which allows the bees of a queenless colony a chance to feed a queen. At one time I kept young queens in a series of cages something like a top-bar, every two inches of the top-bar containing a queen, the whole being placed over a queenless colony, and I think I never knew any of the queens to be starved. I have also kept caged queens in a hive with a laying queen, and generally they are fed, but sometimes I've found a queen dead in her cage.

Loose-Jointed Hive-Bottoms and Supers.

I have a lot of dovetail or lock-cornered hives with Dandenbaker covers and bottoms. The bottoms are in three boards, square joints, which swell and shrink, leaving cracks that can be seen through. The supers have a strip of tin tacked on the ends for the section-holders to rest on, leaving cracks on the sides when set on each other, or on the hive. Is that good enough? MISSOURI.

ANSWER. I should prefer to have all close, still no serious harm can result, unless it should be that the bees are to be hauled and the cracks are large enough for them to crawl through.

CONVENTION PROCEEDINGS

Proceedings of the Colorado State Bee-Keepers' Convention.

(CONTRIBUTED BY THE SECRETARY.)

The 19th annual convention of the Colorado State Bee-Keepers' Association was held in Denver, Nov. 30 and Dec. 1 and 2, 1898.

On the morning of the first day the convention adjourned to the horticultural rooms to hear addresses made before the Horticultural Association, then in session, by Pres. Alston Ellis and Prof. C. P. Gillette, both of the State Agricultural College.

Prof. Gillette's subject was, "Spraying to Destroy Insects Injurious to Fruit;" and in the course of his address he referred to the spraying law, adding that it did no good whatever to spray during bloom, but that it was better to wait several days or a week after the blossoms fall.

The first event of the afternoon session was a paper by Ben Honnett, on

The Bee-Industry of Colorado.

It seems almost like going into the speculations of fairyland to review the bee-industry. There is nothing more fascinating than bee-culture, to my mind (I might except prospecting), from the fact that you may trace the progress of a colony of bees from the time of swarming to its continued succession, and until the result in honey is removed for storage or sale. One becomes, in a manner personally acquainted with each and every colony, noting their individual peculiarities as they progress. The most critical observer will note the fact that success in bee-culture means unceasing care and watchfulness.

The location of an apiary is of paramount importance. The hives should be raised from the ground, a few inches being sufficient to allow air to circulate and prevent dampness. As to the position of the hive—east, west, north or south of the entrance—it is a matter of taste, and plays no important part. The main point is to have the hive fairly sheltered, that is, the hive to have some shade during the hottest part of the day. The ideal location should be one or two hives under each apple tree in an orchard (or any other kind of tree). The feeding-ground should be near an alfalfa field, and where sweet clover abounds, our main dependence being on these plants, and on fruit-blossoms. Very little sweet clover is planted for bee-forage, and this is looked upon with disfavor by the farmers of Colorado. So far as it claims to be a honey-plant, I believe there is none superior. I would rather have an acre of sweet clover for honey purposes than two acres of any other kind of forage.

The habitat of the bee is wherever nectar is to be found, be it much or little. I met bees on the top of Cottonwood Mountain in 1884, when there was no known apiary within 60 miles of the place. The main apiaries are located in the St. Vrain, Big Thompson, Cache La Poudre, Boulder Valley, Arkansas Valley, Arapahoe and Jefferson counties, and in Mesa, Delta, and a few other counties across the range. There are other isolated localities where apiaries exist, but the above-mentioned furnish most, if not all, of the marketable honey.

Those who make a specialty of the business are as a rule wide-awake, intelligent and progressive, catering to the wants of the markets without sacrifice or detriment to the continuance of a well-regulated apiary.

I would right here sound a warning note to the inexperienced, to be careful how they follow the advice of some individuals whose names appear semi-occasionally in the press, recommending semi-invalids to engage in the bee-business, as being light, profitable and healthy. I know of many who have found the bee-business both light and unprofitable, and not so very healthy. It takes persons with their five senses about them to conduct an apiary successfully, altho all must begin sometime; but it should be on a small scale, and then only in connection with some other pursuit.

The result of this season's honey-business is far from satisfactory. In very few cases was there a full crop, some reporting half a crop, some one-fourth of a crop, and a few

no return of surplus. The different localities give various reasons for the shortage. In this section (this side of the range) in May we had frequent showers and cool weather, which interfered materially with the bees flying; then followed severe drouth, which affected the secretion of nectar to such an extent that some of our bee-keepers put their apiaries in winter condition several months before they did last year, there being no late flow. The same trouble existed to a certain extent across the range. Cold nights and rains early in the season produced the same results in many localities.

The quality of the honey crop of 1898 is exceptionally fine. The product of the State for the year 1898 will approximate 700,000 pounds. The demand for Colorado honey far exceeds the supply. Denver, in proportion to population, consumes more honey than any city in the United States.

Altho some have not realized their expectations, nevertheless we must not lag or fall out of the ranks. The future looks bright. The price of honey is fair, and we hope that the next season will meet us again as of yore, ready to assume those responsibilities which fall to our lot in upholding the good name of the Colorado bee-keepers.

BEN HONNETT.

SWEET CLOVER—FOR AND AGAINST.

Mrs. Washburne—How do you reconcile the advantages of sweet clover as a source of honey with its disadvantages in the field, to the farmer?

Mr. Honnett—Agricultural stations are disseminating the idea that alfalfa should be cut early, and it is done to some extent. We must have a permanent source of honey. Sweet clover is carried by ditches to all parts of the farm. On the other hand, it has destructive effects on grain crops. It has so many seeds. Above Arvada is an 80-acre tract containing some wheat, in which sweet clover is a terrible detriment. Millers object to the sweet clover seed. Stock will not eat it except when it is young, and then is when we don't want them to eat it. There are some threats of legislation to put sweet clover among weeds.

F. Rauefuss—Such a law could not very well be carried as long as the agricultural stations recommend it for renovating soils and for hay, especially in Utah.

D. Moon—I kept sowing it until I had four or five acres. It does not hurt the first season, and does not bloom then. The next season it goes to seed. My stock sometimes eat it off entirely. I had it on heavy clay five years, then raised the finest crop of corn I ever saw on that land. Some seasons the bees don't get much honey from it.

Mr. Adams—I have had 20 years' experience with sweet clover, and fed tons of sweet clover hay.

Mr. Honnett—I said that stock would eat it when young.

Mr. Adams—I don't know how young it has to be to be eight feet high, but I have seen that height all eaten off. Why should not the wagon-roads be utilized by growing sweet clover? I know of a large pasture of sweet clover that never gets higher than 6 inches to 2½ feet, as there are enough cattle to eat it all. I have never known stock to have the hooves by eating it, tho they do in the East. As for its injuring grain, that depends on the farmer himself. It won't get high enough the first year, and after that it only does injury if the farmer doesn't plow properly. But it does not harm *our* crops. We don't consider it a weed. It cannot be beaten as a green manure. It is better than alfalfa.

Mr. Honnett—I stated that I would rather have one acre of sweet clover than two acres of any other honey-producing plant.

R. H. Rhodes—I question the amount of the sweet clover honey product. We never have any distinctively sweet clover honey in our locality. But it is the best kind of a fertilizer, and makes one of the best fall pastures. I am acquainted with a cattle man who sowed a patch of wet land to sweet clover. He never had any pasture equal to it. It grew 14 feet high. It is a marvel of feed if only taken care of. It is one of the best adjuncts to a stock farm. Another cattle-man says, "Give me sweet clover more than all other weeds." There is nothing better for preparing the land for potatoes. Put on a log-chain and a four-horse team to plow it up.

L. Booth—I believe the bees do get a good deal of honey from it.

Pres. Aikin—A year ago about one-fourth or one-third of my crop of honey was from sweet clover. The past season it was about two-thirds from sweet clover. I believe it is a good honey-plant.

The minutes of the previous meetings, of the proceedings of the Executive Committee, and of the joint committee of the State Association and the Denver Bee-Keepers' Association on marketing, were then read by the Secretary, and approved.

Mr. C. B. Elliott, the chairman of the committee on marketing, then read his report, as follows:

REPORT ON MARKETING HONEY.

Our committee, with a like committee from the Denver Bee-Keepers' Association, after weeks of labor, and a very careful canvass of this question, concluded that in our judgment the most feasible plan of co-operation in marketing honey was in the formation of a stock company, as outlined on the back of this sheet (which is hereby made a part of our report).

Your committee sent out nearly 300 of these circular letters to bee-keepers throughout the State, at an expenditure for printing, postage, etc., of \$10.90. These circulars were sent out about the first of June. Up to the first of August the committee had received returns from 25 of the 300 circulars sent out, with a guaranteed subscription of stock to the amount of \$160. Of this amount \$55 was from certain members of our committee, leaving \$105 from bee-keepers not members of either committee. Of the full amount of \$160 subscribed, two-thirds was subscribed to be paid in honey, the balance in cash. With such a showing before us, your committee concluded for the present at least to abandon any further efforts in this work.

We very much regret that we are compelled to make such a report, realizing, as we do, the necessity of, and the advantages to be derived from, such an organization.

Mr. Elliott then read the circular letter referred to. It was proposed therein to form a stock co-operative company to be called "The Colorado Bee-Keepers' Exchange," to be capitalized for \$5,000, to be divided into 1,000 shares at \$5 per share, which would give a commercial standing with a fair rating, each share of stock to have one vote, with no voting by proxy; governed by a board of five directors, with a full set of officers; none salaried except those in charge of the company's store-rooms. It was the intention to derive no pecuniary profit other than advancing and maintaining the price of honey; to see that all honey was properly graded; to have a trade-mark, and affix it to all approved crates and packages, both comb and extracted; and to liquefy and repack all extracted honey in some uniform package.

Mr. Honnett: How much honey was shipped from the State this season?

F. Rauchfuss: Eleven carloads of 1,008 cases to the car, besides a number of local shipments from Denver of 25 to 100 cases each.

Mr. Honnett: I was asked if I did not over-estimate in stating the product to be 700,000 pounds.

F. Rauchfuss: No, that is too low.

Pres. Aikin then exhibited several samples of the "German Fibre Package," made by a company in Michigan. It resembles light-brown glazed pasteboard in appearance, and ranges from small sizes up to those large enough to hold 20 or 25 pounds of honey. Mr. Aikin had tested one by filling it with cold water, and letting it stand two weeks. It was not affected in the least. Another, submerged in hot water from 100 to 130 degrees in temperature for eight or ten hours, gave away at the joints. Honey does not affect them. Mr. Aikin had not tried liquefying honey in them by dry heat. They are a little cheaper than lard pails, and fasten with a lid in the same way, but the sides are vertical.

(Continued next week.)

MR. ORVILLE JONES, of Ingham Co., Mich., wrote us Dec. 15 that the bee-keepers in his locality had a fair honey season in 1898.

THE LEAHY MFG. CO. wrote us as follows, Dec. 28:

"We are now, and have been for two or three weeks, running our plant 18 hours a day. It now looks as if we will all have a good trade again."

MR. E. G. MONEY, of Albemarle Co., Va., wrote us Dec. 14: "It gives me much pleasure to renew my subscription to the American Bee Journal. I consider it more than worth the money."

MR. JOHN SUTER, of Seneca Co., N. Y., sent us \$1.00 for the Langstroth Monument Fund, Dec. 17. We hope many more will follow his example—enclose something for that fund when renewing subscriptions.

MR. N. E. FRANCE, State Inspector of Apiaries for Wisconsin, will speak on bee-culture at the Farmers' Institute to be held at Waukesha, Jan. 13. He has been speaking at some institute nearly every day so far this month. Mr. France understands his subject, and knows how to present it.

"DOOLITTLE is sick in bed with the grip, hence his articles will be delayed till he is better." So wrote Mrs. Doolittle, Jan. 2. We sincerely hope our sick friend will very soon be up again. Bee-keepers can't afford to have Doolittle in bed more than just long enough for him to get the necessary sleep and rest—about eight hours of each 24.

MR. DAN CLUMB, of Tulare Co., Calif., has sent us a copy of his local newspaper that copied the whole editorial found on page 728 (1898), entitled "The Union and Comb Honey Lies." It made almost a column in the newspaper. That is a good idea. Try to get your local papers to copy such things from the Bee Journal whenever you can. It will all help to undo the mischief done by the oft-repeated falsehoods concerning comb honey that have appeared in the past.

MR. H. R. BOARDMAN, in a very interesting account of a visit among bee-keepers, reports in Gleanings that he found in Lansing, Mich., J. H. Larrabee, formerly so well known in bee-circles, engaged in the bicycle business, and he finds it more reliable than bee-keeping, which he has about given up. A. D. D. Wood, who went to California to rear queens on the isolated island of Catalina, he found in a smith-shop before a hot fire, where he could not stop, even to talk bees.

MR. THOS. W. COWAN, editor of the British Bee Journal, wrote to his paper from California, Nov. 16, expressing his own and the thanks of his family for the many expressions of tender sympathy received on account of the loss of their son and daughter in the wreck of the Atlantic liner Mohegan, as announced in these columns some two months ago. Mr. Cowan, in speaking of their sorrow, wrote this beautiful paragraph of trust and submission:

"At first our trial did seem almost overwhelming, but very soon we were able to recognize our Father's loving hand in it all, by the assurance He sent us that all was well with our dear ones. Their bodies were so quickly recovered absolutely unharmed by the cruel rocks they had been tost among, and the beautiful look of holy calm upon their faces testified that they had died as they had lived, and to their entrance into Glory, so that we could not but feel that, altho taken from us, they were present with the Lord. So our hearts were comforted, and we felt indeed that they were not lost, but gone before."

York's Honey Almanac is a neat little 32-page pamphlet especially gotten up with a view to create a demand for honey among should-be consumers. Aside from the Almanac pages, the forepart of the pamphlet was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample for a stamp; 25 copies for 40 cents; 50 for 60 cents; 100 for \$1.00; 250 for \$2.25; 500 for \$4.00. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

United States Bee-Keepers' Union.

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee \$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., E. Whitcomb; Vice-Pres., C. A. Hatch; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GEN'L. MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

VOL. 39. JANUARY 12, 1899. NO. 2

NOTE.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England: Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

The Dot Diagram Contest that we run during December, 1898, closed Jan. 1, as announced. Next week we expect to be able to give the result.

General Items department of the Bee Journal is suffering from an overplus of contributions, and those who have so kindly sent in reports will please be patient, as we expect to accommodate all as rapidly as possible.

Only 16,000 Copies of last week's American Bee Journal were printed. We presume that was the largest single edition of any bee-paper ever issued in this country. Of course, we will use a good many of them for sample copies during this month. With the present improved appearance of the old American Bee Journal, and the rich contents that it will have this year—well, we believe it deserves just about double its present circulation, and ought to have it in a very few months.

Not a Candidate. A letter received from Hon. R. L. Taylor, of Lapeer Co., Mich., dated Jan. 5, reads thus:

FRIEND YORK: If convenient will you say in the American Bee Journal for next week, that I am not a candidate for President of the National Bee-Keepers' Union for the coming year, and cannot act as such.

Fraternally yours, R. L. TAYLOR.

The readers of the Bee Journal who are voting members of the Union mentioned, will please note Mr. Taylor's announcement. He usually means what he says.

Inventive (?) Beginners in bee-keeping are often impressed with the idea that they ought to get up a better hive than was ever invented by all the learned bee-keepers that existed before them. Strange that the bump of invention of some people develops so rapidly when once they become bee-keepers. But it is even so, for the United States Patent Office records show that nearly 1,000 applications for patents on hives have been filed in this country. And yet perhaps less than a half-dozen of those hives were of any permanent value.

Mr. U. Gubler, a noted European bee-keeper—and evidently a sensible one—offers this advice to beginners, in a late issue of the *Revue Internationale*:

"The bee-keeper who knows how to handle tools likes to try to make his own hives, and therein we have only words of encouragement. But let him confine himself to systems approved by the experience of our masters. Refrain from a tendency to make new things, to introduce pretended improvements, before knowing thoroughly the nature of the bee and its needs. The hives that we possess are the result of the studies, the experiments, and the discoveries of a great number of bee-keepers and experts of all lands; and to desire to make new is simply to render one's self liable to pay dearly for the experiments that others have made before us."

The Roll of Honor mentioned last week as being originated by Gleanings, began in the number of that paper for Jan. 1. There were 17 names as a starter. Quite a number of them refer to the American Bee Journal as being where they first saw the writings of Mr. Root. And that reminds us that nearly all the bee-papers that have been started in this country, and that amounted to anything, were practically built up on the American Bee Journal as a foundation. We could name several bee-papers of to-day whose editors gained a reputation by first writing for these columns, and thus "getting in" with bee-keepers who read.

Whether it is an honor or not, it seems to be true, that the old American Bee Journal has been used quite often as a stepping-stone by those who aspired to fill an editorial chair in bee-journalism.

And yet, after having lighted other apiarian torches, the "Old Reliable" appears to shine undimmed, if not with more resplendent lustre than ever before.

The Langstroth Monument Fund.—Hon. Eugene Secor, General Manager of the United States Bee-Keepers' Union, has undertaken to help push through to a finish the laudable work of raising the fund for the erection of a suitable monument for the lamented Langstroth—the Father of American bee-keeping. We have received this communication from Mr. Secor, which we trust will be carefully read by all our subscribers:

FOREST CITY, IOWA, Jan. 2, 1899.

Having been placed on the Langstroth Monument Committee, I wish to make this final appeal to the bee-keepers of America, before erecting the slab that is to mark the resting-place of the most noted character and best-loved bee-keeper in our country.

It seems to me that if we neglect this opportunity to do honor to his name we shall always regret it.

Bee-keepers ought to esteem it not only a matter of loyal duty, but a loving privilege to contribute to a suitable monument to one whose services to American apiculture have been so universally acknowledged.

It is one of the strange things in this world, that very often the inventor of useful appliances fails to receive the rewards due to his genius. Thus it was in Langstroth's case. He builded, we occupy.

The world now recognizes his services, but robbed him of the material fruits thereof when needed.

Will this generation be satisfied to let him lie in an obscure or forgotten grave when it is understood that the ingratitude, selfishness, and envidia of jealous rivals

darkened for a time the lustre of his achievements, and marred the happiness of a grand good man?

The committee has in preparation an inscription to be engraved on the monument, which recognizes the great services rendered by Father Langstroth, and which attempts to pay loving tribute to his memory. It is to be dedicated to him by the bee-keepers of America.

It is neither just nor wise that a few men should erect this memorial, when every one interested in bees or bee-keeping is reaping the fruits of Langstroth's genius.

A large number of subscriptions in amounts not to exceed \$5 each would be a better recognition than a few large contributions.

If every reader of these lines who has not already done so would immediately send in his or her contribution to this fund, it would relieve the committee from the embarrassment of erecting a monument which they feel is in no sense an adequate expression of the admiration and love felt for the Father of American bee-keeping.

The committee will proceed in the spring to erect such a memorial slab as the funds in hand will warrant, and if the reader does not in the next few weeks send in his mite, he will miss the opportunity and privilege of being counted as one of the donors.

Sincerely,

EUGENE SECOR.

Now let all who have not already done so, send their contributions to Mr. Secor, or to the American Bee Journal office if more convenient. If sent here, we will forward to Mr. Secor, who will send a receipt for all moneys received. Better attend to it very soon, and not be left out of one of the best opportunities of your life to show honor to one of the noblest men of this greatest of all centuries.

Testimonials which speak in high praise of the American Bee Journal and its editor's humble efforts have just poured in upon our desk the past month or so. Why, we never saw anything like it before. To say we appreciate all the expressions of appreciation of our work is to put it very mildly. But we can hardly feel that we merit them. We should like to print all the kind words that have been sent us, but that would be utterly impossible. Please accept our sincere thanks for such kindly expressions.

The Bee and the Horticulturist is the title of an address delivered by Editor Abbott before the Missouri State Horticultural Society, and published in his paper, the Modern Farmer and Busy Bee. It is an able discussion of the relation of bees to horticulture, and the delivery of such an address before the leading horticulturists of a State cannot fail of bringing good results. Editor Abbott is doing no little to spoil General Manager Secor's chances for paying lawyer's fees in Missouri.

The National Bee-Keepers' Union.—The 14th annual report of this organization, for 1898, is on our desk. We hope soon to be able to publish the principal part of it, which shows that General Manager Newman had the usual number of troubles to settle during the past year. And the usual success seems to have attended the undertakings of the old Union. We notice the membership for 1898 was 149, and that there is \$170 in the treasury.

York's Honey Almanac will hereafter take the place of our "Honey as Food" pamphlet. The new pamphlet contains 32 pages, with regular almanac pages, and a neat calendar for the year 1899 on the front cover page. Send a two-cent stamp for a sample, to the Bee Journal office. It is a neat honey-seller, and will be preserved by all who get it.

Apiculture as a Branch of Agriculture is more and more recognized. The December number of the Ruralist is chiefly occupied with bee-culture, J. O. Grimsley being the regular conductor of that department.

A Separator-Cleaner is mentioned in the Progressive Bee-Keeper by F. L. Thompson, which cleans the separators "by simply drawing them through between two knives made of files, held pretty firmly together by springs and a treadle, so that both sides are scraped at once."

Don't Place Bees Along a South Wall. L. P. P., in Revue Eclectique, gives a sad experience with bees placed against a south wall. The hot sun beating on the hives, with the additional heat reflected from the walls, melted the combs of a colony into a heap. A north wall is safer.

Bees in a Bag. In moving bees, D. L. Shangle puts most of the bees in a two-bushel bag with a screen bottom to give air, and also to feed if the bees are confined long. After the journey, the bees are returned to the hive. He finds this safer in hot weather than to have them crowded in the hive. Gleanings.

An Uncapping-Box that gave great satisfaction to Rambler is thus described in Gleanings: "It was five feet in length by about 18 inches wide, six inches deep, with a wire-cloth bottom. Set at an incline it would hold the cappings for two days and drain them nicely. I like an uncapping-box of this shape. It does not require frequent removing of the cappings. The cappings of to-day can be spread out in the evening and drain out all night; then the next morning these cappings can be crowded to one end of the box for further draining through the day, and removed at night to the sun extractor."

Bees Dying on the Snow. G. M. Doolittle says if the cause is diarrhea, the bees might as well die on the snow as anywhere. If from the sun shining in the hive, put a board before the entrance, and its shade will prevent the bees from coming out until it is 45 degrees in the shade, at which temperature, if still, and the sun shining, the bees can rise from the melting snow. Novices are unnecessarily alarmed at seeing dead bees on the snow, many of such being brought out of the hives by the living bees when the weather allows house-cleaning, and 100 bees make more show on the snow than 10,000 on the bare ground. Gleanings.

Fast Work at Extracting Honey. Giraud-Pabou, being somewhat skeptical as to F. Boomhower's report of 1,800 pounds of honey extracted in three hours by two men, wrote to Mr. Boomhower, in New York State, asking how it was done, which reply convinced Mr. Pabou there was nothing incredible about it. Mr. B. puts Porter escapes under the supers in the evening, supers of combs are taken from the apiary on a wheelbarrow, honey extracted before sealed, a four-frame reversible Cowan extractor used, and the honey ripened in a tin tank. One colony produced 400 pounds of comb honey, largely from red clover, and an apiary of 70 colonies produced four tons of comb honey. Revue Internationale. An average of 114 pounds of comb honey is not bad for the season of 1898.

Fences and Plain Sections. Ten pages of Gleanings for Dec. 15, 1898, are taken up with a symposium on fences and plain sections. The editor strongly favors them, and thinks the adverse reports are due to the faulty construction of supers or fences. Cross-cleats were made by some $\frac{1}{4}$ -inch wide, by others $\frac{3}{4}$. The Roots struck a golden mean, but found it was a mistake, and now have adopted 5-16. The thickness of the cleat has been reduced from 2-12 to 2-13, in order to be on the safe side. The editor is convinced of his mistake in believing that the separator should come flush with the top of the section, and the 1899 fence will drop $\frac{1}{4}$ -inch below the top of the section. J. E. Crane says bees finish sections toward the close of season more rapidly with the fence than with the old-style separator. He found the sections, whether plain or old-style, when used with the fence, were filled of such even weight that they could be sold by the piece more satisfactorily than sections with old-style separator. F. L. Thompson used sections and separators of both kinds in the same super. More pop-holes could

be counted in the old, but in appearance there was no difference, and he pronounces the fence a failure. He thinks the scheme of doing without separators, altogether more promising than that of using fences. Glue didn't hold his fences. The objections made in the Canadian Bee Journal are mentioned, and the American Bee-Keeper is credited with having been fair, altho taking a somewhat neutral attitude. Editor Root gives half-tones of two of the late Mr. Morton's fancy honey, "life size," that are fine as pictures; also a picture of eight old-style sections that are fine, for which he says he hunted long and hard; and a picture of four of Danzenbaker's 1898 fence honey.

How Much Heating will make Foul-Broody Honey Safe to Feed? Dr. Miller advised not less than 150 minutes. R. L. Taylor thought 15 minutes enough. Editor Root, less definite, advises boiling "several minutes." Dr. Miller, in *Gleanings*, gives his reason for not feeling safe with boiling so short a time. Prof. Mackenzie heated spores of foul brood to 212 degrees, and kept them at that point for two hours, and then secured growth. In other words, two hours' boiling did not destroy the spores, and the doctor says: "While not inclined to dispute in the least that you may have safely fed infected honey that had less than 15 minutes' boiling, with my present light I don't feel safe to advise anything less than boiling 2½ hours."

Hives. In discussing in the *Progressive Bee-Keeper* the right kind of a hive, R. C. Aikin favors the shallow divisible brood-chamber, two or three sections, each 15 inches square and five inches deep. Doolittle follows, and says this is theoretical bee-keeping, for Aikin has not had experience with these shallow chambers, and by the time he has had as much experience as Doolittle he will not favor them so much. Doolittle says he has modified his views somewhat as to the size of hives. For 20 years he managed successfully the smallest brood-chamber in existence, averaging nearly 100 pounds of comb honey annually; but having purchased an apiary with 10-frame Langstroths which he has worked in an out-apiary, he thinks he would now prefer the 10-frame Langstroth to the 9-frame Gallup where cellar wintering could be practiced. For five years he has had hives larger than 10-frame Langstroths, but sees no advantage in them.

Saving Strayed Queens.—It sometimes happens in taking off supers that a queen will be taken with the bees that remain in the super, and if several such supers have been piled up together it is not easy to tell whence the queen came. Fred S. Thorington had an interesting experience in that line. He put the cluster of bees out in the open air without protection in the day, covering them with a blanket at night, leaving them without food. Two days later they circled in the air like a natural swarm, and went to what he supposed was the hive the queen came from. The idea seems to be to let them swarm like a hunger-swarm, and trust to their going back to their own hive. The only question would be whether, in a case where the workers came from a number of different hives, they might not return to the hive from which a large number of workers came, thus taking the queen to the wrong hive. *Progressive Bee-Keeper*.

A Section-Cleaner made by John S. Bruce is thus described by F. L. Thompson in the *Progressive Bee-Keeper*: "The framework is the same as that of Mr. Aspinwall's, but the roller, about two inches or over in diameter, consists essentially of a rasp made by punching holes in a sheet of tin with a ¼-inch fine chisel. The center is a core of wood, and between the wood and the tin rasp are T tins, forming a number of little alleys into which the propolis falls, and is punched out occasionally with a wire. The superfluous roughness is taken off the rasp by turning it with a file until it has acquired just the right degree of cutting surface to remove propolis and do smooth work. On the same level with the roller is a knife made of an old file, which, when the section is past along to the rasping roller, first cuts away any large-sized chunks of propolis or wax. It is so near to the rasp that one end of the section is passing over the rasp before the other has left the knife; and on the other side of the rasp is another roller, covered with emery-cloth over felt, also quite close to the rasp. All being on the same level, the section passes over the knife, the rasp, and the emery-cloth, at one operation and one sweep. The edges are cleaned just like the sides, strips between and on each side of the rollers forming a table above the level of which the rollers slightly project."

United States' Bee-Keepers' Union.

General Manager Secor's report for 1898, which is in the hands of the members, reads as follows:

Report of the General Manager for 1898:

FELLOW BEE-KEEPERS:

It is considered one of the legitimate purposes of this Society to promote legislation in the interest of bee-keepers.

Acting on that idea the Executive Committee appointed three delegates to attend the Pure Food Congress, held in Washington, D. C., beginning March 2, 1898. The delegates consisted of E. T. Abbott, of St. Joseph, Mo.; Dr. A. B. Mason, of Toledo, Ohio; and your humble servant, the General Manager.

The object of the Pure Food Congress was to unite all producers and all manufacturers of food products, and all societies and people that believe in the necessity or desirability of protecting the public against adulteration and misbranding of every article intended for food, drink or medicine, consumed by man.

Believing that in no other way could this society so speedily and effectually bring about the results it is seeking to achieve, Mr. Abbott and myself attended that convention.

We were greatly pleased, not only with the number of delegates present, but the representative character of the men: Scientists of national reputation; leading physicians and pharmacists; pure food commissioners from many of the States; intelligent and progressive farmers; representatives of wholesale and retail grocery and confectionery associations; and many other organizations and interests were represented by able and earnest delegates, solely in the interest of purity of all articles of human consumption.

What was accomplished at that congress is more fully explained by Mr. Abbott in his paper, "The Busy Bee," and copied in the *American Bee Journal*, March 31, page 200, and my own report published in the last-named paper, on page 216.

In April last I got a letter from Frank Gilmore, Watertown, Conn., enclosing a letter from a law firm of his town in which Mr. Gilmore was notified to remove his bees within 15 days under a threat of prosecution and injunction. The complaint was, that the aforesaid bees destroyed the entire crop of peaches, raspberries, and other fruits on the premises of a neighbor; that they stung horses and visitors, and otherwise annoyed the neighborhood.

I gave Mr. Gilmore such advice as I thought best suited to his case, and presume he escaped the clutches of the law, as I heard nothing further from him.

During the same month, Mr. Baldwin, of Mexico, Mo., sent me an account against a Chicago commission house, saying he could get no pay for honey billed to the firm. I at once began correspondence with the commission men, and after a couple of letters got a draft in full. Mr. Baldwin expressed himself as entirely satisfied with the transaction, and donated to the Union two years' membership in advance.

Ed Gerould, of East Smithfield, Pa., was threatened trouble from a neighbor who was determined to spray his peach orchard while in full bloom, altho it had been explained to him that by so doing his neighbor's bees might be poisoned. Mr. Gerould wrote me for advice and help. I sent him some printed matter and advised him how to proceed, which was the last I heard of that matter.

Chas. Haise, a quiet, peaceable, unoffending person who lived in Atlanta, Ill., received from the Marshal of the town the following notice in June, 1898:

"SIR—You are hereby notified that your bees, situated and kept on the premises now occupied by you, have become and are a nuisance to the neighborhood and public, and you are hereby notified to abate, remedy, or remove the same immediately as provided by ordinance. A failure to do so will subject you to a penalty of not less than \$300.00."

The Union was appealed to by Mr. Haise and his neighbor bee-keepers. The trial had already been set, and only three days remained in which to get my advice to him regarding a plan of defense. But it proved sufficient. The case was dropped when the prosecutor found an organization with money, courage, and law behind the defendant.

The bee-keepers interested expressed their gratitude for the prompt and efficient aid rendered by the Union, and said they believed the case was dismissed because of its assistance. No money was expended by the Union in this matter.

An effort was made before the Western Classification Committee to rescind the rule instructing all railroad agents to refuse bees by freight in less than car lots. I put up the best argument I could think of by letter, but failed. The rule still stands, I believe. Mr. Aiken went before the Committee in person, by request of the President, for the same purpose.

At a meeting of the Board of Directors held in Omaha, Neb., in September, 1898, the General Manager was authorized to commence legal proceedings against the adulterators or counterfeiters of extracted honey, if, in his judgment,

such action was likely to be productive of good to bee-keepers.

Considerable correspondence has been carried on preparatory to such action, but the evidence and aid necessary to make it seem advisable has not yet developed, and no suit has yet been brought.

The Editor of the American Bee Journal called my attention to an article in a New York metropolitan journal giving credence and publicity to the old fable about comb honey being extensively manufactured without the aid of the honey-bee. The article stated that paraffine was largely used for making the comb which was filled with glucose syrup and put upon the market to deceive the public.

At the request of the Editor I sent an article to the New York paper, with a purpose to correct the error and if possible give the public some facts and opinions on the nature and use of honey.

As my reply was copied in full in the American Bee Journal, page 728, I will only say that it brought out a very satisfactory public retraction, and a personal letter from the editor asking for literature bearing on the subject of honey. I mailed her (the editor was a woman) Dr. Miller's pamphlet on the food value of honey, and I believe one other editor will be more careful in her public statements about manufactured comb honey.

If the past year has brought no signal triumph at court, the labors of the General Manager have been varied and abundant. He has been appealed to in behalf of every threatened bee-keeping interest, public and private.

Were it not for the modern blessings of phonography and typewriting machines, he could not have performed the duties of the office with any satisfaction to himself, to say nothing of pleasing those for whom he works.

Fraternally yours

EUGENE SECOR,

General Manager.

Forest City, Iowa, December, 1898.

We see by the financial statement that there is \$175 in the hands of the Treasurer. There are about 450 members now belonging to the new Union, as shown by the list of members accompanying the General Manager's annual report.

The Root Co.'s Column

Readers of the American Bee Journal:

We do not propose to come at you with hammer and tongs, nor to talk you to death; but as the Root Co. has bought this column paid cash for it we want to

BLOW OUR OWN HORN,

Not in our own Journal, but in that of the other fellow. We are going to try to make this column interesting, and, incidentally, tell you about our wares;

Gleanings in Bee-Culture,

TWO PAPERS FOR THE PRICE OF ONE.

For \$1.00 we will not only send you Gleanings one year, but also your choice of any of the following papers also for one year: THE AMERICAN AGRICULTURIST, weekly; THE O. J. FARMER, weekly; THE NEW ENGLAND HOMESTEAD, weekly; FARM JOURNAL, monthly; THE POULTRY - KEEPER, monthly. Or for \$1.10 we will send Gleanings one year, and one of the following papers also one year: THE OHIO FARMER, weekly; THE MICHIGAN FARMER, weekly; THE PRAIRIE FARMER, weekly; and THE PRACTICAL FARMER (Mr. Terry's paper) weekly. These offers are good to either old or new subscribers, but all back subscriptions, if any, must be paid at \$1.00 per year, as we believe in treating all alike.

Look out for this space next time.

Send your orders to

The A. I. Root Company
MEDINA, OHIO.

SWEET CLOVER

And Several Other Clover Seeds.

We have made arrangements so that we can furnish Seed of several of the Clovers by freight or express, at the following prices, cash with the order:

| | | | | |

| Alfalfa Clover | 60c | \$1.00 | \$2.25 | \$4.00 |
| White Clover | 70c | 1.25 | 3.00 | 5.75 |
| White Clover | 80c | 1.40 | 3.00 | 5.00 |
| Alfalfa Clover | 60c | 1.00 | 2.25 | 4.00 |
| Crimson Clover | 25c | .90 | 2.00 | 3.50 |

Prices subject to market changes. Add 25 cents to your order, for cartage, if wanted by freight. Your orders are solicited.

GEORGE W. YORK & CO.

118 Michigan Street, CHICAGO, ILL.

Report for 1898 Red Clover.

I commenced the spring of 1898 with 35 colonies, and workt for both honey and increase. I obtained 1,200 pounds of comb honey, 350 pounds of extracted, and increase to 68 colonies, by natural swarming. Only prime swarms were hived.

Why do bee-keepers lament because their bees do not work on common red clover? Do they not know that there is nothing in it that the honey-bee wants? The mammoth red clover produces good honey, and all our honey-bees can reach the nectar, altho the corolla is far longer and deeper than in the common red clover. I never saw any honey from common red clover—only thin, red stuff. Thin as water.

I have taken the American Bee Journal for nine years—ever since beginning bee-keeping—and I would not like to do without it. THEO. REHORST, Fond du Lac Co., Wis.

Great Honey-Eaters.

I do not want to miss a single copy of the American Bee Journal, even if you did treat most unmercifully on my pet corn last week, on page 777, in commenting on the death of Carl Maynard. You say:

"We believe we never before heard of three persons eating a pound section of honey at one sitting. Of course it may be done, but why should any one want to fill up with so much sweetness all at once? People ought to use common sense in eating as well as in everything else."

Now, I have not only heard of three persons eating a pound section at one sitting, but I have often seen two persons eat that quantity. I am a bachelor, and keep bees, and when I am taking off honey it often happens that a friend drops in and takes dinner with me, and I never knew any

honey left from a pound section placed on the table on such occasions; we would sometimes get on the outside of that and part of another one. I think it depends a great deal upon how well one likes honey, and what he eats besides. Our bill of fare would consist of about the following:

Bread, milk, butter, meat, fruit and honey. The meat and fruit would often remain untouched. We ate the honey because we liked it, and why should we not? It is good, wholesome food, and nobody ever intimated that we were eating beyond the bounds of reason!

My usual ration is one pound a day, three meals; therefore, my guest must have eaten about two-thirds of a pound; yet I never thought he was a glutton. I was glad to see him enjoy it.

I agree with you, that it is not probable the honey had anything to do with the death of Mr. Maynard. On the contrary, he died in spite of the effect of the honey.

My experience, and that of every man I have talkt with on the subject is, that comb honey is a tonic in its effect. That is, if one is troubled with constipation, a diet of comb honey will give relief. I know one man on whom it acts as a purgative. Extracted honey might have the same effect.

Hurrah for the American Bee Journal! But please do not impugn the good sense of me and my neighbor because we like honey.
H. D. MURRY,
Rankin Co., Miss.

[Mr. Murry, we take it all back. We thought we could eat a good deal of honey at one sitting, but you can beat it. What a sweet capacity—or what a capacity for sweets some people have!

Yes, we are in favor of everybody eating lots of honey—but not so much at one time as to sicken, or kill.—EDITOR.]

A Beginner's Experience.

I have read the American Bee Journal for the past year and have become very much attacht to it for the many excellent pointers that it has given me on the care of bees.

A year ago last summer a swarm alighted on a tree in my neighbor's yard. He said that he would not bother with them and if I desired I might have them. I borrowed a musty hive stored in the cellar of another neighbor, and with fear and trembling I lived my first swarm of bees. It was a late swarm, so I took no honey from them the first year. Last year was a very poor one, and I could take no honey from them again, but I have had very much pleasure studying their habits, and putting into practice some of the very excellent suggestions found in the American Bee Journal.
T. H. SONNEDECKER,
Seneca Co., Ohio, Dec. 12.

Poor Season—Deep Frames.

This has been a poor year for honey in this vicinity. The spring was all right and my bees built up as well as might be expected, considering that half of them were weak. White clover bloomed well, and altho the bees work on it faithfully, it took too long to make a trip, so they got only enough to keep up the brood, until towards the last there came three days of an old-fashioned honey-flow, and they packed the brood-nest full, and some of them started above, but that was the end of it. Had it not been for a little white aster that grows profusely, and blooms in September, on mused lots around the edge of town, I should have had to call on the sugar barrel to feed my bees.

Well, Dr. Miller and others can harp about sticking to the standard frames, till all is blue, but I'm through with them. The way was this. I had been contemplating changing to a deep frame for several years, but the job lookt so big that I put it off until the past summer, when I finisht up the job, and I never want another like it. Now

T. F. BINGHAM, Farwell, Michigan.

BEST EXTRACTED HONEY FOR SALE.

ALL IN 60-POUND TIN CANS.

ALFALFA HONEY.

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

BASSWOOD HONEY.

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms in Wisconsin. It has a stronger flavor than Alfalfa, and is greatly preferred by those who like a distinct flavor in their honey.

Prices of either Alfalfa or Basswood Honey:

A sample of either, by mail, 8 cents; samples of both, 15 cents. To pay for package and postage. By freight, one 60-pound can, 8 cents a pound; two cans, 7 1/2 cents per pound; four or more cans, 7 1/2 cents per pound. Cash must accompany each order. If ordering two or more cans, you can have half of each kind of honey, if you so desire. This is all.

ABSOLUTELY PURE BEES' HONEY,

The finest of their kind produced in this country.

We would suggest that those bee-keepers who did not produce any honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere. "YORK'S HONEY ALMANAC" will be a great help in locating customers for honey. See prices on another page.

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.

Please mention the Bee Journal when writing Advertisers.

my bees are all in cypress hives, 14 1/2 inches inside, and the same in depth. The body is in two parts horizontally, and the extracting surplus case the same as a half body, so the frames are interchangeable for brood or surplus, and the brood-chamber can be small or large to suit circumstances. The frames are spaced by wire staples, and hung by wire nails on metal rabbits—not much chance for glue in that arrangement. Oh, I've got the management down fine—all I want next year is an old-fashioned crop.

There is nothing the matter with the American Bee Journal. I've had about all of them (bee-papers) and the American Bee Journal is the best for me.

THOS. THURLOW,
Lancaster Co., Pa., Dec. 13.

Something to Correct Fermentation.

Sometime, somewhere, I have seen, that there is something we can put in honey (extracted) that shows a tendency to ferment, or "work," as we sometimes say, and smells and tastes a little sour around the top of the jar, at the edges, a slight, white frothiness. Has any one seen or heard of any such remedy? 'Tis said it will arrest fermentation and sweeten the honey. Is this so? And what is it? I saw such a statement some time ago, but I cannot now recall when or where. I think it was some sort of an acid.

STEPHENSON CO., Ill. A. W. HART.

Wintering All Right.

We have cold weather here now. My bees are getting along finely. I built a shed for them four by eight feet, and am wintering seven colonies.

B. F. SCHMIDT,
Clayton Co., Iowa, Dec. 15.

Small Honey Crop.

My honey crop was small the past season—about 1,000 pounds of comb and 300 pounds of extracted, from 225 colonies. I had to feed about 900 pounds of honey and sugar to keep my bees to the middle of May, as I find it better to feed in the fall than early in the spring. My bees were put into the cellar Nov. 30. We have had good sleighing and steady winter the past three weeks.

C. THEILMANN,
Wabasha Co., Minn., Dec. 15.

Wintering in Double-Walled Hives.

Bees are wintering now. The weather is bright and sunshiny, with about six inches of snow, and not very cold. During the honey season I got only half a crop, as it was too dry here. My bees are on the summer stands, and will have to stay there this winter, the only protection being a double-walled hive. If they have plenty to eat, and are not disturbed, they will winter all right. I have 55 colonies.

M. J. RISTLER,
Allen Co., Ind., Dec. 15.

Doing Well with Bees.

I have 15 colonies of bees now, and have had 75 at one time. I have been in the business seven years, and am now doing well. I give them only my spare moments, as I am a contractor and builder. I get 16 and 20 cents per pound here for my honey.

LUKE W. SIMMONS,
Pope Co., Minn. Dec. 14.

Favors the Plain Section.

The white clover was plentiful in bloom the past season, but no honey, or not as good a yield as in 1897, but I got a fair crop from buckwheat. My bees are in good condition for winter, with plenty of stores, and I hope they will come out all right in the spring.

I tried the plain sections this year, and find that they are all right. I find a better sale for the honey at 10 cents a section, as

JUST READ WHAT THEY ARE:

Offer No. 1.—Samantha at Saratoga.

100,000 Sold at \$2.50 per copy.

This is indeed a feast of fun, by the only peer of Mark Twain's humor—JOSIAH ALLEN'S WIFE (Marietta Holley.)

Read this Extract from the Book:

And right here, let me insert this one word of wisdom for the special comfort of my sect, and yet it is one that may well be laid to heart by the more opposite one. If your partner gets restless and oneasy and middlin' cross, as pard-

ners will be anon—or even of tene—start them off on a tower. A tower will in a cases out of 10 lift 'em out of their oneasiness, their restlessness and their crossness.

Why I have known a short tower to Slab City or Leontown net like a charm on my partner, when crossness wuz in his mean and snappishness wuz present with him. I have known him to set off with the mean of a lion and come back with the limment of a lamb.

And jest the prospect of a tower ahead is a great help to a woman in rahn' and keepin' a partner straight. Somehow jest the thought of a tower sort of lifts him up in mind, and bappitys him, and makes him easier to quell, and partners must be quelled at times, else there would be no livin' with 'em.

She takes off FOLLIES, FLIRTATIONS, LOW-NECKED DRESSING, DUCES, PUG DOGS, TOBAGGANING, ETC.

Opinions of Noted Critics:

"Exceedingly amusing."—Rose E. Cleveland. "Delicious Humor."—Will Carlton. "So exuberantly funny, we had to sit back and laugh until the tears came."—Witness. "Unquestionably her best."—Detroit Free Press. "Bitterest satire, coated with the sweetest of exhilarating fun."—Bishop Newman.

Nicely bound in paper, fully illustrated, printed from new type and on fine paper. 370 pages. Postpaid, 40 cents.

Offer No. 2.—Gleason's Horse-Book.

By Prof. Oscar R. Gleason.

This is the only complete and authorized work by America's king of horse-trainers, renowned throughout America and recognized by the United States Government as the most expert and successful horseman of the age. The whole work comprising History, Breeding, Training, Breaking, Buying, Feeding, Grooming, Shoeing, Doctoring, Telling Age, and General Care of the Horse. You will know all about a horse after you have read it. No one can fool you on the age of a horse when you have this book. 416 pages, bound in paper, with 173 striking illustrations produced under the direction of the United States Government Veterinary Surgeon. In this book Prof. Gleason has given to the world for the first time his most wonderful methods of training and treating horses. 100,000 sold at \$3.00 each. Our price, postpaid, 40 cents.

Offer No. 3.—The Poultry-Keeper Illustrators.

The four "Poultry-Keeper Illustrators" are the greatest books on poultry subjects ever issued, and are a veritable poultry dictionary, covering the ground so completely that, having these four books, one needs scarcely anything more except "grit" to become a successful poultry-raiser. You cannot get such other books in the whole world, not even for \$50 each, for they do not exist. Were they given in another form and elaborate binding and colored cuts you might think them easily worth \$5 each, but what you want is not elegant printing, and in these we give you the value in information that you can make use of. They have cost much in labor and cash, but you get all this value for almost nothing. We mail the 4 Illustrators for 40 cents.

Illustrator No. 1.—Poultry Houses, Incubators, Brooders, Coops, etc., 25 cents.

Illustrator No. 2.—Artificial Incubation, Raising Chicks, Testing Eggs, etc., 25 cents.

Illustrator No. 3.—Poultry Diseases, Lice, Grapes, Moulting, Egg Eating, etc., 25 cents.

Illustrator No. 4.—Judging Fowls, Description of Breeds, Mating, etc., 25 cents.

Address **GEORGE W. YORK & CO., 118 Michigan St., CHICAGO, ILL.**

they are lighter in weight. They were not filled as well as they should be, for on an average they weighed about 12 ounces per section. I dare say the plain section will take the lead in 1899, altho this was a very poor year to test them, on account of the poor honey crop. W. H. HEIM.

Lycoming Co., Pa., Dec. 12.

Report for 1898.

I value the American Bee Journal very highly. I started in the spring of 1898 with six colonies of bees, increased to 19 and sold \$32 worth of honey. If you would call that good luck, then I owe it all to the instructions I receive through the American Bee Journal. ARNOLD S. REEVES.

Cheboygan Co., Mich., Dec. 15.

Honey-Dew for Winter Stores.

The past season was practically a failure here. I got about 140 pounds of buck-

wheat honey. There was a great deal of honey-dew in this part of the country, and I think, generally speaking, that there was more or less of it left in the winter stores, and I will predict a great mortality among the bees in this section. I was very careful to see that there was none of it left in mine. My bees had their hives full of good buckwheat honey, and never went into winter quarters in better condition.

Venango Co., Pa., Dec. 15. ED JOLLEY.

Quite Cold Weather.

Bees apparently up to date are doing well. The weather has been quite cold, the coldest morning registering six degrees below zero. I think in this locality, and I think I may say safely in the county, the honey crop is all disposed of. We are looking forward to and making preparations for next year's harvest.

The American Bee Journal comes regularly on each Thursday evening, and a wel-

come guest it is. It is like an old and tried friend, and I can tie to it. Long may it live to bless and gladden the hearts of those who take it and contribute to its pages.

Clark Co., Wis., Dec. 15. L. ALLEN.

A Section Scraper, Etc.

My report for 1898 is the smallest I have had since I commenced keeping bees, six years ago; but it is not bad in comparison with my neighbor bee-keepers.

I had 40 colonies, spring count, and 1,801 full sections, making an average of 41 sections to the colony.

There has been a great deal said of late about a section-cleaner made of an old sewing machine and sandpaper or emery wheel. I have an instrument made out of a section of an old mowing machine. It is the greatest labor-saving tool there is in the business. When I take off a surplus case of honey, before I take out a wedge, while everything is tight and solid, I scrape

the tops of the sections and then the pattern-slats, and it does not take more than a minute or two; then I have nothing but the bottoms and edges of the sections to clean. For cleaning old, dirty hives it is just the thing; you can get into the corners and pretty nearly plane it out as clean as new.

I have been taking the American Bee Journal for six years and have every number bound.

Nov. 26 I put into the cellar 60 colonies in a little better condition than I ever saw them before. With the aid of "Langstroth on the Honey-Bee" and the "Old Reliable," I hope to keep improving. For a man of 68 years, I think I did remarkably well, seeing that I never had any instruction except from the bee-literature named.

DANIEL SMETHURST.

Crawford Co., Mo., Dec. 17.

Honey a Scarce Article.

My honey crop was about 200 pounds this year from 90 colonies, but my bees are in fine condition, and all in the cellar. Honey is a scarce article here. C. A. GOODSELL, Blue Earth Co., Minn., Dec. 12.

Short Honey Crop.

My honey crop was short the past season. From 50 colonies of bees I had 1,000 sections of salable honey, which brought me \$70, or about 7 cents a section. It is basswood honey. White clover bloomed profusely, but secreted no nectar. D. C. WILSON, Linn Co., Iowa, Dec. 15.

A Poor Season.

I could not keep bees without the Bee Journal. The past was a poor season here. Last spring I had 28 colonies, increased to 39, and took 700 pounds of honey, but it was

all dark and not very salable. I sold five colonies and have 34 this winter. I lost one last winter out of 30.

Blair Co., Pa., Dec. 7. S. H. STOFFER.

Results of the Past Season.

My report this year is a ton and a quarter of surplus comb honey from 40 colonies, spring count, and 48 colonies now.

McKean Co., Pa., Dec. 12. G. H. BOYD.

Corneobs as Smoker Fuel.

The past season was too wet for a honey crop in this part of Missouri. I secured a fair crop the last three weeks in August, and have had a good demand for comb honey at 12 1/2 cents per pound.

Gentry Co., Mo., Dec. 15. J. E. ENYART.

BUY THE BEST.

If you want the best low-down Wagon you should buy the Electric Handy Wagon. It is the best because it is made of the best material; the best broad-tired Electric Wheels; best seasoned white hickory axles; all other wood parts of the best seasoned white oak. The front and rear hounds are made from the best angle steel, which is neater, stronger and in every way bet-

ter than wood. Well painted in red and varnish. Extra length of reach and extra long standards supplied without additional cost when requested. This wagon is guaranteed to carry 4,000 pounds anywhere. Write the ELECTRIC WHEEL CO., Box 10, Quincy, Ill., for their new catalogue, which fully describes this wagon, their famous Electric Wheels and Electric Feed Cookers.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Jan. 9. The trade is not active in comb honey, many of the retail dealers being supplied with sufficient stock to meet demands for some time to come. Prices are quite steady with 13c for best white, off in color, etc., including amber grades, 10 1/2-12c; dark, 9c. Extracted 6 1/2-7c for white; amber and dark, 5 1/2-6c. Beeswax, 27.

R. A. BURNETT & Co.

DETOIT, Jan. 2. No change in supply of honey as to quality, but prices are somewhat lower than last quotations, viz: Fancy white, 13c; No. 1, 12 1/2-13c; fancy dark and amber, 10 1/2-11c. Extracted, white, 6 1/2-7c; dark, 5 1/2-6c. Beeswax, 25 1/2-26c.

M. H. HUNT.

SAN FRANCISCO, Dec. 28. White comb, 9 1/2-10 1/2c; amber, 7 1/2-9c. Extracted, white, 7 1/2-8c; light amber, 6 1/2-7c. Beeswax, 24 1/2-25c.

There are no changes to record in the condition of the honey market, stocks being light, as previously noted, of both comb and extracted, with market firm at current values. Business is naturally greatly restricted, and at present is almost wholly on local account. Considering the light yield this season, the aggregate of exports to date is of very liberal volume.

COLUMBUS, Dec. 29. No improvement in demand for honey; market is quiet and barely steady at 12 1/2-13c for fancy white, 10 1/2-11c for No. 1, and 8 1/2-9c for dark.

COLUMBUS COM. AND STORAGE CO.

INDIANAPOLIS, Jan. 4. Fancy white comb, 12 1/2-13c; No. 1, 10 1/2-11c. Demand fairly good, dark comb honey is being offered at 8 1/2-9c with almost no demand. Clover and basswood extracted, 6 1/2-7c. Beeswax, 26 1/2-28c.

WALTER S. POWDER.

NEW YORK, Jan. 2. The market is well supplied, especially with dark. Demand is fair for white and dark, and off grades are being neglected. We quote:

Fancy white, 12 1/2-13c; No. 1 white, 10 1/2-11c; amber, 9 1/2-10c; dark, 7 1/2-8c. Stocks of extracted of all kinds are light. White, 6 1/2-7c; amber, 6c; dark, 5 1/2-6c. Southern, in barrels, 60 to 65c per gallon. Beeswax dull at 26 1/2-27c.

HILDRETH BROS. & STOCKEN.

REBELE, Jan. 6. Our honey market is very quiet. Finest 1-pound white fancy combs move slow at 12c often 11c; excellent grades, 9 1/2-10c, and dark, poor, etc., 6 1/2-8c. Extracted, 5 1/2-6c. Beeswax, fancy pure, 28 1/2-30c; dark, etc., 24 1/2-26c.

BALDERSON & Co.

CLEVELAND, Jan. 2. Fancy white, 13 1/2-14c; No. 1 white, 12 1/2-13c; No. 1 amber, 10 1/2-11c; No. 2 amber, 9 1/2-10c; buckwheat, 8c. Extracted, white, 7c; amber, 6c; buckwheat, 5c.

A. B. WILLIAMS & Co.

Convention Notices.

Wisconsin.—The Wisconsin State Bee Keepers' Association will hold their annual convention at Madison, Feb. 9 and 10. It promises to be the best held for years. Every bee-keeper is urged to be present. An interesting program is being arranged. Platteville, Wis. N. E. FRANK E. Sec.

Minnesota.—The following program has been arranged by Pres. E. B. Huffman for the meeting of the Southern Minnesota Bee-Keepers' Association, which meets in Winona, Minn., Jan. 25 and 26:

- Opening address—Pres. E. B. Huffman.
How to prepare bees for winter, and the proper way to care for them—Frank Yahnke.
How to prepare a colony of bees for the introduction of a queen, and the best way to introduce her—C. A. Gile.
Which is the most profitable to work for, comb or extracted honey, and the most suitable size hive for the same?—E. B. Cornwell.
What is the best size of hive, frames and sections for general use?—S. W. Judge.
The best way to manage bees for increase—W. F. Martin.
What is the best way, and the kind of hive to use, in stimulating bees, and also feeding them?—John Turnbull.
Winona, Minn. C. A. GILE, Sec.

Page & Lyon Mfg. Co.

NEW LONDON, WIS.,

Operates two Sawmills that cut, annually, eight million feet of lumber, thus securing the best lumber at the lowest price for the manufacture of Bee-Keepers' Supplies...

They have also one of the LARGEST FACTORIES and the latest and most improved machinery for the manufacture of Bee-Hives, Sections, &c., that there is in the State. The material is cut from patterns, by machinery, and is absolutely accurate. For Sections, the clearest and whitest Basswood is used, and they are polished on both sides. Nearness to Pine and Basswood forests, and possession of mills and factory equip with best machinery, all combine to enable this firm to furnish the BEST GOODS AT THE LOWEST PRICES.

Send for Circular and see the prices on a full line of Supplies.

Eastern Bee-Keepers!

Seven years ago we started an Apian Supply business in NEW YORK CITY, as we saw an opening here. That we made no mistake in this is shown by the large demand for supplies and our constantly increasing trade. Our aim was to furnish supplies promptly. In many cases bee-keepers find the freight on supplies from the Western factories is as much as the cost of the goods. In buying near home you not only save freight, but get your goods much more promptly. We keep several carloads of

Hives, Sections, Foundation, Etc.,

always in stock ready to ship, and the prices will be found right. We also run two apiaries for honey and sell BEES AND QUEENS. If you expect to use anything in the Apian line the coming year, you will do well to send for our Catalogue. We would be pleased to quote you SPECIAL PRICES on what you want, as this is our mill season, and we can afford to sell for small profits. Hives, Sections, etc., are made in Wisconsin, where lumber is low, and the best can be had.

Our Special Price on Foundation, Hives and Sections will make you Smile.

Write for it, stating the quantity you can use. DEALERS should write for our 30 discount sheet which is now ready to mail.

CONTRIBUTED ARTICLES

No. 2.—The "Golden" Method of Producing Comb Honey Described.

BY J. A. GOLDEN.

[Continued from page 4.]

IN order to fully understand this method, I herewith present a cut of a hive-body, one super, bottom-board and queen-cage.

First, then, if you will notice, the bottom-board has what we call a "rim" lying on it. This rim is $\frac{1}{4}$ -inch thick on the outside edge, and beveled down on the inner side, and is a little wider than the edge of the side-board space and division-board. The side-body is $\frac{7}{8}$ thick, space $\frac{3}{8}$, and a division-board or inside board $\frac{3}{8}$, making $1\frac{3}{8}$ inch; the rim $1\frac{7}{8}$ wide, the beveled edge giving a $\frac{3}{8}$ -inch space to the side passage-way. Then when preparing hives for wintering this rim is turned upside down, and when the hive is set on it, it completely shuts up the side entrance, making it a dead-air chamber from below. (I will note the temperature further on.)

To form the side entrances in a new hive, take strips $\frac{3}{8}$ -inch square, and tack one in each inside corner of the hive-body; then a $\frac{1}{4}$ inch or $\frac{3}{8}$ board as long as the inside of the hive is tacked on the $\frac{3}{8}$ corner strips, letting the board be flush or even with the side-body of the hive at the bottom, and even with the top of the brood-frames, or within $\frac{1}{4}$ inch of the side-body of the hive. (See engraving for side entrances and division-board, showing the bottom of brood-chamber.)

Now, reader, can you not see wisdom in this construction of a hive? Suppose there were two stairways leading up to a gallery—one was crowded with people and the other was comparatively free, and you had a load of honey to carry up, which of the two ways would you choose? Your answer would be, "The one that was not crowded, every time." And think you that the busy honey-bee is void of wisdom? Nay, verily, the honey-bee possesses largely of instinct, for the Creator has made it so.

I will now describe the super, which you will notice in the engraving. It differs from the general super in use only by cutting a $\frac{1}{4}$ -inch rabbet on the top of the end-board (see engraving), and the side passage-way is made the same way as in the brood-chamber. The $\frac{3}{8}$ -inch strips are tacked in the inside corners, then tack on the same thickness of board as in the brood-chamber, letting it come even with bottom, and within $\frac{1}{4}$ inch of the top of the side-body of the super, or as high as the top of the sections. Thus when the super is placed on top of the brood-chamber, the side passage-ways come opposite each other, and thus you see the side entrance

is continued from the bottom to the uppermost super; also the $\frac{1}{4}$ inch bee-space entering each super is continuous.

On the bottom of the end-boards of the super a 1 16 inch groove is cut $\frac{1}{4}$ inch wide, to receive a strip of sheet-iron $1\frac{1}{4}$ inches wide, reaching across the super and letting the ends in the super sides 1 16 inch, then tacks are driven in, thus leaving the bottom of the super level. This apron is for the section slats and separators to rest on when placed in the super. And when slats are placed in the super, a wedge strip is dropt down at each end of separators. When the sections are in, two more wedge strips are pushed down, one at each end, which tightens the sections (see illustration); also a side-wedge, if necessary.

The $\frac{1}{4}$ -inch deep rabbet cut on top of the super end-board is to be as wide as the rabbet on the end-boards of the brood-chamber, which will be noticed farther. (See illustration.)

The queen-cage which you will observe extending in the super, is made $\frac{1}{4}$ -inch narrower than you use, having a partly-drawn comb or foundation in it, and is covered on

Hive-Body, Bottom-Board, Super and Queen-Cage.

both sides with wire-cloth, cutting the cloth $\frac{1}{2}$ -inch larger all around, then folding the $\frac{1}{2}$ inch over, tacking on the prepared cage with $\frac{1}{4}$ -inch wire tacks, leaving one corner to spring back, to let the queen run in or out, as desired. □

I here present a view of my combined cover and feed receptacle, and I am here to say that it is one of the essentials to have in all apiaries. It is made from $\frac{1}{4}$ or $\frac{3}{8}$ inch lumber, and fitted to the inside dimensions of the hive-body. A strip $\frac{1}{4}$ inch thick and $1\frac{1}{2}$ inches wide is laid under each end of the cover, then tacked fast to the cover and tacks

clincht. Bevel the top edge of the cover all around, as this will admit the super rim to rest down and not catch on the feed cover.

A box made from $\frac{1}{4}$ or $\frac{3}{8}$ inch lumber, 3 inches deep, 10 inches wide, and 15 inches long, is set over the center and tacked fast. From the bottom of the feed-cover a rim made from $\frac{3}{8}$ -inch lumber is made 10x15, and little strips of tin tacked across the corners on top to hold the frame in square, then cover the frame by tacking on a cover of wire-cloth, after folding the edges of cloth; then hinge the frame to the box by a strip of cloth or thin leather. On the inside of the box, close to one end, bore six or eight $\frac{3}{8}$ -inch holes, and when not in use lay over the holes a little strip of board, and at the opposite end of the box tack two little cleats, then tack on a thin strip of board, making a pocket to keep your slate or diary for recording dates of swarm, and amount of surplus of that colony.

The end strips that were clincht on the end of the feed-cover, when placed on the hive or super, rest in or over the rabbets, making a bee-space over the top of the frames and supers. Two other strips $\frac{1}{4}$ -inch thick and $\frac{7}{8}$ or one inch wide is fitted over the top of the side-entrances in the hive-body, then place the feed-cover on the brood-body, and pass a couple of screw-eyes down through the feed-cover and strips into the division-board on each side. This is used thus for wintering, making the side-entrance a complete

Combined Hive-Cover and Feed-Receptacle.

dead-air space. Those strips are taken off in the spring and laid one on each side of the feed receptacle and screwed fast to the feed-cover, ready for use when desired.

This combined cover and feed receptacle is always to remain on the hive, or on the supers when the latter are on the brood-body—always ready for its use.

A 5-inch super rim (which is shown back of the food receptacle) is placed on over the combined cover, then an outside cover. Let me note here, during the hottest weather, should there be any fears of combs, either brood or surplus, melting down, slip a little stick under the outside cover, raising it $\frac{1}{4}$ or $\frac{1}{2}$ inch, and I will guarantee no combs to melt down, either in the brood or surplus I care not how hot Old Sol shines, for the passage-ways encircle the entire colony above, beneath, and between and he that hath an eye to see please take notice that ventilation controls the heat and hastens evaporation; and if the problem of ventilation, not drafts, is better or more perfectly solved than as set forth in the Golden hive and method, I kindly ask for its publication, for in these latter days apiculture keeps pace with all the industries of progression, and will continue so long as time is extended to mortals like bee-keepers of the present generation; and he who says apiculture has reacht its highest attainments surely is not wise.

Morgan Co., Ohio.

Emptying Unfinisht Sections—Honey of Italian Bees vs. that of Blacks.

BY EDWIN BEVINS.

WITH editorial permission I will poach on Dr. Miller's preserves to the extent of telling "New York" (see page 711, 1898) why his bees failed to clean out those unfinisht sections.

If I were in the habit of betting I would stake a pint of cider that all the unsealed honey in those sections was carried downstairs in a small fraction of the two weeks. "New York" left the sections on the hive. Then the bees were too lazy to uncap the sealed portions of the honey, and so long as it was close at hand they did not care a continental whether this sealed honey was in the brood-frames or in the supers, and they did not know anything of "New York's" intention to take it away.

When he found that this sealed honey was not going below, he should have used the uncapping-knife on it. Then his sections would have been cleaned out in short order, if the weather had been warm enough. It is best not to delay this work too long. If you do, however, you can get the sections cleaned during the sunny days of early spring. The cappings with the adhering honey can be saved in shallow boxes. If these boxes are placed in empty supers over the brood-frames, and the cappings occasionally stirred, the bees will clean them nicely, and nothing is lost.

DO ITALIANS STORE BETTER HONEY THAN BLACKS?

In answer to the question of Mr. Bartz, on page 718 (1898), I will say that I cannot tell why Italian bees store a better quality of honey than do other bees. It has been my belief and contention all along that there is no appreciable difference when all bees store from all sources alike. This would be plain to Mr. Bartz, if in printing my last article on this subject, somebody had not suppress the first half of one of my sentences, and printed the other half as if it belonged to the preceding sentence, thus rendering my meaning very obscure. Mr. Bartz would not then have askt me to account for a thing which I believe has no existence.

When it is once an understood and accepted fact that Italians store their honey from different and better sources than other bees, there will be no need of asking why this honey is of better quality than that of other bees. The answer is obvious.

It is most natural for one who has not been a close observer of the habits of the different kinds of bees for a long period of time, to suppose that all bees store from the sources within easiest reach, and that one kind of bees will get about as much honey from any one source as another kind. If observation has demonstrated the fact that Italians neglect those flowers which secrete the poorer grades of nectar, and store only from the flowers which secrete the better grades, then we know why the quality of Italian honey is *sometimes* better than that of other bees. But let all kinds of bees be confined to one source of supply—say white clover or basswood—and who is able to affirm that the honey of Italians will be any better than the honey of blacks or hybrids?

The superior quality of Italian honey (if it is superior) must be accounted for by the fact of selection (if it is a fact) when liberty of choice can be practiced. In this way only can I answer the question of Mr. Bartz.

Decatur Co., Iowa.

New Device for Closing Hive-Entrances.

BY L. KREUTZINGER.

EFFORTS to facilitate preparations of bees for transportation have led me to bring before the bee-keepers an entirely new fixture. It is a device by which the hive-entrances can be closed at a rate of 100 per hour, without disturbing the bees in the least, and without the use of a hammer or any other kind of tool whatever.

As it is solely designed for the purpose of closing up hive-entrances, we may call it an "Entrance Closer."

The accompanying illustration shows its position when attacht to the hive. The Closer consists of two parts made of perforated zinc sliding against each other by means of the framed enclosure thereof. Thus, when slid together, the "Closer" has a length of a fraction less than 12 inches, and adapted to the 8-frame hive. For 9 and 10 or larger hives, it needs only to be extended the desired length. For the old "box hive," where the entrance is but 8 inches or

less in length, only one of the two parts above mentioned will do.

But not only as to the length of the entrance this device accomplishes the purpose, but also particular attention has been paid to the height thereof. The "Entrance Closer" is arranged to cover and fit any kind of an entrance, whether narrow or high, short or long, from $\frac{1}{4}$ to $\frac{7}{8}$ of an inch in height, and from 2 to $1\frac{1}{2}$ inches in length.

It is further provided with steel plates or strips, each of the front ones having a screw, and connected by threaded rods with the rear ones, thus forming a forklike shape (crank), and serving for the firm attachment to the hive-wall.

When inserting, the strips have to be down on the bottom-board, slide the rear strips (or plates) behind the hive-wall, the perforated zinc thus remaining leaned and prest

The Kreuzinger Entrance-Closer.

against the hive; then turn the strips upright to the position as shown in the illustration, screw by hand each screw in both the strips against the zinc and hive-wall, and the entrance is closed. It is done in shorter time than it takes to read these directions.

When separating, loosen both screws, turn the strips from their upright position down to the bottom-board, and the "Closer" will slide out.

No tool of any kind is necessary, no hammering, or any waste of material, such as tacks, screen wire, etc.

Bee-keepers who practice transporting their bees from and to their out-apiaries, and those who are in the business of buying and selling bees, will find in this device a great convenience and a handy contrivance lasting them for years. It is durable, and owing to its material being of zinc it will not rust.

Cook Co., Ill., Jan. 10, 1899.

Adulteration of Foods—Are We Likely to Get Laws on the Subject?

BY C. P. DADANT.

THE interest which our bee-keepers have shown at all times in this question shows that it is one of great importance to them. Indeed, if it were not for the adulteration of honey, and the fear of adulterated honey from the buyers, this article would probably be twice as valuable and of much more ready sale than it now is. Not only fraud supplies an increase in quantity, but this increase in quantity is also of less quality, and thus harder to dispose of.

Then the knowledge of existing adulteration creates a prejudice which, very often, as we all know, attaches to the true product, since even the very finest article of comb honey has been often suspected by uninformed, or rather ill-informed, parties.

From time to time this question of laws on adulteration has been brought before the public, but never yet, in this country, in as persistent a way as at present.

About 1880 my father was appointed by the Western Illinois and Eastern Iowa Bee-Keepers' Association to draft and circulate a petition to Congress upon this matter. The petition was sent out and finally put before Congress with something over 10,000 bee-keepers' signatures; but it was, like many other things, buried without hope.

Now, we bee-keepers are not in the lead; the druggists, the dairymen, the consumers in general, have preceded us and joined with us to help put an end to the nuisance of adulteration. A National Congress was called last year, another has been called for this year, and the States are also awakening to the necessity of action; for an Illinois Congress was called but a few weeks ago. But little real good has been done so far, for it takes time to organize to get a footing, so as to carry a weighty influence into a legislature; but the ball has been set a-rolling, and it is hoped will not be stopt until the task is done.

It strikes me that a National enforcement of pure food laws is a necessity for success. State laws, differing in each individual State, can only be make-shifts of temporary standing and of imperfect action. Then it would be necessary to have, as in Europe, where such laws exist, inspec-

tors, whose sole duty should be to see that the laws are enforced. There is nothing that can be objectionable in a law compelling the sale of an article under no other than its true name, and such a law ought to be enforced in every State uniformly. State sovereignty, on such questions, since the abolition of slavery, has always seemed to me to be no more than a farce, and the inhabitants of one State ought to have no more right to do wrong than those of another. What is right in Iowa cannot be wrong in Illinois, morally at least.

Some years ago Missouri had no law compelling a girl to obtain her parents' consent to her marriage before she was 18 years of age, and rash young ladies of the Sucker State were known to cross the Mississippi with their lovers, when matrimonially inclined, for the sole purpose of evading a law which did not agree with their plans. Either it was wrong for a girl to marry without her parents' consent, before she became of age, or the Illinois law was wrong.

If we have a State law on adulteration in Illinois, and they have none in a neighboring State, may not the violator of the law establish himself where he will find the greatest freedom to perpetrate his frauds?

I believe the time is close at hand when we will obtain some satisfaction on this subject. When the public spirit is ready for a reform, it takes but little time to bring it about, tho it sometimes takes a long agitation to mature the popular mind on questions involving great interests. But on this subject there is, or will be, but little open opposition. The adulterators themselves want to appear honest and fair, and the only points they will dare raise will be technical points of constitutionality or law, which ought not to stop an important reform like this.

Many reforms and many new things are on the public mind, some of which will probably not mature for decades. But some, like the hard-road question, will be pushed to a solution by private enterprise in many places, even before the country takes hold of them, thus showing plainly that they are ripe and must be carried through.

Meanwhile, let us all put a shoulder to the wheel. Propagandism is the only way to push a reform to completion. If you believe a thing is right, do not let it rest, do not cease to speak of it, to push it, to advise it until it is done.

Hancock Co., Ill.

Several Things Noted and Commented Upon.

BY WM. M. WHITNEY.

EDITOR YORK:—I have read what you say about scribblers, etc., in connection with your reference to "The Story of Bee-Farming" in the Youth's Companion, which story I read sometime ago, and, novice as I am, it was difficult to suppress a smile. While I endorse all you say on the subject referred to, yet I desire to add that crudeness is not confined entirely to the writings of novices in bee-keeping.

WHEN BASSWOOD YIELDS BEST.

As, for instance, in an article on "basswood bloom," there appears the following on page 769 (1898):

"The condition most favorable for a large yield of nectar is when the weather is very warm and the air is filled with electricity. At times when showers pass around with great display of lightning," etc.

Now, I imagine a broad smile lighting up the face of an electrician, on reading that statement. Having been taught that in a dry, cool atmosphere is the place to look for superabundance of electricity, he will be surprised to find the laws of Nature so revolutionized as to completely reverse the order of things.

SINGLE-WALL VS. DOUBLE-WALL HIVES IN WINTER.

And in another article in the same number of the Bee Journal, on the care of bees in winter, while inferentially condemning the double-wall hive, the writer gives instructions for wintering bees in single-wall hives, which, in principle, is the same thing as the double-wall excepting the front, which, being unprotected, must in very cold weather result in severely taxing the energy of the colony.

My bees are in double-walled hives, and are packed snug and warm, and there isn't a single day when the atmosphere is suitable for them to venture out, that they are not on the wing, whether the sun strikes the front of the hive or not; and I will go him a "Pound Sweeting." In ounces to the pound that in the same locality my bees will show

their noses at the hive-entrance sooner than his will; for, if his hives are painted white, as they should be to protect his colonies from the excessive heat of summer, no winter sun will thaw out his bees through that board, but they will be obliged to depend upon their own internal warmth and the atmosphere outside, while mine are already warm, and are only waiting a favorable opportunity to fly. So much for that.

CRUDENESS IN APIARIAN LITERATURE.

An editorial in another bee-paper refers to a "pair of stairs," and in judging a honey exhibit says, "I should have believed the judge was *impartial* or *unfair*." Now this may be a slip of the pen, or a typographical error, but it doesn't look so. Many other things could be referred to, but I forbear.

There is plenty of literary crudeness, not chargeable to novices, but published over the signatures of would-be-considered experts. But what am I doing? Guess I'm not feeling very well; in fact, I'm not, for I drank a cup of coffee before retiring last night, and did not sleep well. But let us change the subject.

Being past the age of active business life, I have plenty of time to devote to my bees, and either working for or studying them, nearly my whole time is given. While I have read many works on apiculture several times carefully, and while I read all the current literature on the subject obtainable, yet there is much to be learned by actual experience.

TWIN QUEENS—COLOR IRRITATING BEES.

Some one in last week's Bee Journal reports finding twin queens, and asks if any other person can report a like instance. I had just that experience last summer. A cell was found as long as my little finger, and well formed. I watched it with much curiosity till the time for the queen to emerge had past, when I opened it and found two queens nearly fully developed, but dead.

In my experience in the bee-yard my opinion will have to go with the minority in the "Question-Box" respecting the color of garments worn irritating bees. My habit is to go to my bees with whatever I happen to have on, and my apparel is as likely to be black as anything else; and I have not yet discovered any change in their disposition. It may be that any garment rough or woolly would cause some irritation; yet my bees are so very gentle, as a rule, that no tendency in that direction has been noticed.

At the September meeting of the Board of Trustees of the Insane Asylum, located here, after dinner it was proposed that we go out and take a look at the bees. There were several ladies in the party, many of whom, as well as gentlemen, were dressed in black. We went without smoker or veil, but I suggested that if any desired protection, veils would be furnished; they however concluded to risk being stung, so we went with no protection whatever. I lifted several hive-covers to show them section-cases and extracting-supers, then took them to a colony which had no such appliances, one which I was building up with a young queen which for certain reasons I thought much of; after uncovering the brood-chamber, I lifted frame after frame filled with brood and covered with bees; examined them from side to side, finally finding the queen, picked her from among the bees with my fingers, showed her around among the company, and put her back, replaced the frames in the hive with not the slightest demonstration of anger from one of them; in fact, the bees seemed to admire the variety of colors worn by the different members of the party.

No, my experience is entirely against the theory, that it makes any difference what color one wears. I think the fact that most woollen goods are of a dark color, or black, has created the impression that the color causes the trouble, when in fact it is the texture of the garment, if anything.

I believe bees possess the sense of smell extremely developed, and that they recognize their master by it as completely as a dog does his. I know mine do. I can put my hands on the lighting-board, and they will run out and smell of my fingers, and go back perfectly satisfied; and the more I handle them, if it is done gently, the more familiar and quiet they become.

O! I'm a crank, all right enough. I have a *lot* of things to tell you, but guess I've bored you enough at this time.

Kankakee Co., Ill., Dec. 12.

[Mr. Whitney did not write the foregoing for publication—only for the editor's eyes—but gracefully consented to its appearance in print, when we requested it. —EDITOR.]

CONVENTION PROCEEDINGS

Proceedings of the Colorado State Bee-Keepers' Convention.

(CONTRIBUTED BY THE SECRETARY.)

(Continued from page 23.)

DISCUSSION OF QUESTIONS.

QUESTION—Has any one tried the Golden method of producing comb honey, and with what success?
No one present had tried it.

HONEY STORED BY FOUL-BROODY COLONY.

QUESTION—Can we sell section honey from a super filled by a foul-broody colony?

W. L. Porter—It is very rarely that a super is filled by such a colony.

Mr. Adams—There is a fine in the foul brood law against selling such honey.

FLAVOR OF ALFALFA HONEY.

Mr. Booth—It is said that alfalfa honey has no distinctive flavor. Is this true of it any more than of other honeys? I cannot tell by tasting where honey comes from.

Pres. Aikin—Prof. Gillette once asked me to tell by tasting what a sample of honey was. I guest fruit-bloom. Then he said it was sugar-honey. He said perhaps he was not an expert at tasting, as his sense of smell was defective, and he had come to think that smell and taste went together. I have determined the source of honey by the smell of the raw nectar, and also by dissecting bees and tasting the honey-sacs. Alfalfa honey is not decided in flavor, but mild. Cleome honey has a decided flavor, and so has sweet clover honey; as Mr. Rhodes says, it tastes like cinnamon. I was told by a firm here in Denver that they could ship in a little white clover honey, mix it with a good deal of alfalfa honey, and sell it for white clover.

Mrs. Booth—I cannot tell the difference between the perfume of the blossoms of red clover and alfalfa. I have asked several to shut their eyes and try, but they could not tell. I don't think the dark and purplish honey is cleome honey, as it is said to be. I don't get any purplish honey, tho I live in the midst of miles of cleome.

H. Rauchfuss—Don't you get green-colored honey?

Mrs. Booth—No.

J. Cornelius—My crop was at least two-thirds cleome honey, and was a very dark green.

(Samples of Mr. Cornelius' honey were shown, both comb and extracted, and were of a decided green tint.)

COLOR AND TASTE OF HONEY.

Mr. Porter—I have had a good deal of experience with cleome honey. It is always of a greenish cast. This can be seen in the sections. It has a very little bitterness, not disagreeable. I have noticed a liquid oozing from the bark and leaves of the plant, leaving a residue. This has a decided flavor of cleome honey.

H. Rauchfuss—I think the presence of pollen in honey gives the color. The pollen of cleome is perfectly green. Bees working on the blossoms become green all over, and soon die. They fringe their wings by pitting them against the hard and sharp stamens in getting the nectar.

Mr. Booth—A dozen persons might bring in honey, and I would wager considerable that we could not tell the sources of it.

F. Rauchfuss—Such a sampling of honey was carried out at the Omaha meeting, and the committee made very few mistakes, only three or four.

Mr. Booth—I don't want them to see it, only taste it.

F. Rauchfuss—Out of a number of samples of the same color only one was erroneously estimated.

Mr. Honnett—Why should there not be some who cannot distinguish tastes, just as others cannot distinguish colors? Railroad committees examine for color-blindness.

Pres. Aikin—There is a vast difference in tasting-powers. You couldn't fool me on buckwheat honey if I was blindfolded.

Mr. Porter—You couldn't fool me on basswood honey. But it depends on training the observing-powers. I have

extracted some apple-blossom honey: it has a very distinct flavor, like the aroma of apple-blossoms. The best way to determine the source of honey is to extract some when unripe, then observe and cultivate the taste.

DO BEES NEED SALT IN BROOD-REARING?

QUESTION—Do bees necessarily have to have salt in brood-rearing?

Walter Martin—It is not absolutely necessary, but I think they ought to have access to salt in some form.

J. E. Lyon—I never do without salt for the bees in some form. I put from a teaspoonful to a tablespoonful of a solution of salt at the entrance. It soon dries up, but the deposit does not blow away.

Mr. Adams—Salt *is* necessary. But in this country the bees get salt from the water.

Mr. Honnett—Bees are fond of salt. Sometimes a swarm which has absconded from a hive will stay in the same hive after it has been washed with salt-water.

Mr. Rhodes—The question is, Do they *need* salt? An Eastern writer says men and cattle don't need salt. For proof, he says the cattlemen in the West don't give salt. But our cattlemen do buy and distribute salt.

H. Rauchfuss—We formerly salted our bees, and they dwindled a great deal in the spring. Lately we have not done so, and the bees have done considerably better.

Dr. McLean—Physicians say it is impossible for life to exist without salt. Bees are like other animals, therefore they require salt. They will procure more or less in what they eat. Salt exists in almost every food.

COLONIES SLIGHTLY AFFECTED WITH FOUL BROOD.

QUESTION—What would you do with a colony having just a little foul brood at this time of year, the hive being very strong with bees and honey?

Mr. Adams—Let them alone until spring.

H. Rauchfuss—When can you handle bees in spring without risk? Kill them. You can buy bees for \$2.00 a colony. Boil the honey, and buy bees with the proceeds.

Mr. Booth—It is against the law to get the money for that honey.

H. Rauchfuss—The law only says until disinfected.

Mr. Martin—Can the honey be taken from such hives so as to be first-class, or salable at all?

Pres. Aikin—The flavor is destroyed by the heat.

David Bates—I have had considerable experience with foul brood. If I had such a colony as is described, I would set it aside and burn the whole thing. If you leave it, you are liable never to get rid of the disease. A neighbor who has been treating it has had it continuously four or five years. He has kept the whole country alive with it. The only safe way to handle foul brood at this time of year is to burn the whole thing.

Mr. Lyon—There is too much monkeying with foul brood in my neighborhood. It doesn't pay. I would kill it out. Five out of ten colonies will be robbed out before spring, regardless of the present strength of the colonies.

Mr. Bates—I have been in the bee-business over 45 years. I have had it come up in my yard again and again. I have tried to save the colonies infected, but have only made a bad matter worse. They get weak and are robbed, and spread the disease over the yard and the neighborhood. If 100 sections were on a hive, I would not save any of it.

Mrs. Booth—My honey won't burn.

F. Rauchfuss—Make a pit, set the hive over it, and after everything has burned that will burn, bury the rest.

BEES TAXABLE AS PROPERTY.

QUESTION—What authority have you for thinking that bees are taxable as other property?

A lengthy discussion followed, which it seems best to summarize. Some thought that as bees could not be identified they could not be taxed, and expressed surprise that any one should want his bees taxed, even if they were property, as no object was apparent in having them taxed; and pointed out that frequently bees were not taxed by assessors. To these objections it was replied that the reasons bees are often not taxed are either that they are often considered insignificant, or that freedom from taxation is considered an inducement to bee-culture; that runaway bees can be claimed if not lost sight of, and could be recovered if identified, just as horses are; that in general it is not a question of identifying, for bees are generally in hives, not out of them, and hives may always be identified; that if bees were not property, inspectors could not inspect, nor bee-keepers' proceedings be published at the expense of the State, nor

would money be invested in bees, instead of in something more secure; and that if bees were not property, they could not be protected by law.

SECOND DAY.

The following paper was read by Mr. Ben Honnett:

Improved Apicultural Appliances.

There is an urgent necessity for an article upon this subject, to elicit the discussion necessary to a formal conclusion. There is a wide divergence of opinion with reference to appliances, so-called *improved*. Starting with the Langstroth improved hive are several objections; that is, the brood-frame resting in wood saw-kerf, which causes many of them to become broken and troublesome at the busiest time. Another is the raised rabbet all around the brood-chamber, which frequently breaks off on being pried loose from the super. The Wisconsin is an improvement in this respect, as it allows the super to be slid on without injury to the bees, which in itself is a great consideration where time is essential.

We next find many other hives patterned in a great measure after Langstroth's, to-wit: the Wisconsin, the Wisconsin-Improved, the Heddon shallow or Heddon deep, all having their supporters. In my humble judgment a movable-frame hive is correct, no matter what the make.

So again we have the preference shown in size, some advocating 8-frame and others 10-frame hives. From my own experience I prefer 8-frame hives, for this reason: They are more easily handled, the super is more quickly filled and more readily refilled when a good honey-flow is on. There being more medium-sized swarms than extra-large ones, is another good reason for 8-frame hives. Of course I do not for a moment believe this is the only hive that is good. I would say that the particular hive that a bee-keeper fancies is more apt to give him good results than any other, from the very fact of his being predisposed in its favor (providing always the frames are movable), the main consideration being the result in honey.

Beginners are more apt to be misled about hives than the old bee-keeper. It is a notable fact that almost every novice in bee-keeping makes an attempt to revolutionize the business, which, according to his or her idea, has been conducted on erroneous principles, hence we have the large variety of hives. I have bought bees at various times, and accumulated Langstroth, Langstroth-Grimm, Simplicity, Langstroth-Improved, Wisconsin, Heddon, and others; my preference being the Wisconsin, which I have found to be simple to operate and producing good results. I know it is touching a ticklish spot for me to mention this fact, and it will arouse considerable discussion (and that is what we want with reference to the best hive), so I will leave the subject and proceed.

The various makes of supers also have many divers admirers. I have tried the T, the pattern-slat, and some of my own make, the latter having bars across the super instead of the T, the same allowing only bee-space to enter the super. They work fairly well, but I prefer the pattern-slat to any other, for this reason: the sections fit the slat to a nicety, and this super keeps the sections cleaner than any other, which is very desirable, as those having plenty of propolis to remove will readily appreciate. Of course the follower can be wedged up to a nicety, thereby giving the bees a minimum of space to gum up.

I have been using separators for two seasons, and tho I have not met with the success that was desirable, I am satisfied that those running their apiaries for comb honey should not do without them. My hives being mostly the Wisconsin, I use the thin wood separator scalloped at the bottom, as I found many that had not been scalloped gnawed at the bottom, thereby evidently wasting time which should be otherwise employed.

I carefully examined a new device called the fence separator, which is intended for sections especially prepared, without bee-spaces. I object to the fence separators for the following reasons: They are not practicable, nor are they profitable to use. A change must be made in every super, giving more width to allow for the separator, which has cleats up and down holding the fence, which are glued, and in this dry climate fall off. The space between the fence is too small, and will cause the bees to enlarge the same, but at the cost of valuable time.

It is claimed by the manufacturer that the square no-bee-space sections produce more uniform and slightly combs than others. That remains to be proven. I feel firmly that they are a delusion and a snare in our line. I believe in

keeping up with the times, but make your experiments on a small scale, so you may avoid disaster. Of course, we understand the animus in most cases the manufacturers find it necessary to get out some novelty, the same as tree-men, charging round prices and getting rid of them as rapidly as possible.

A most careful consideration should be given to any new appliance, in recognizing as a factor the increase in cost and time necessary to handle the same; and most bee-keepers have other business, and give their time, which is rushed in the spring, and is limited. If we could concentrate upon one style of hive and section, the bee-keeper would have solved a problem that has as yet found no solution.

BEN HONNETT.

F. Rauchfuss— I have never been favorably impressed with the plain section and fence. But I would not condemn them until they have been tried. At the Omaha Exposition, I thought the best filled and capped honey, so far as could be judged from the outside of the cases, was a lot of three cases of Minnesota honey, in plain sections. It is another question whether there are advantages enough in these fixtures to justify adopting them.

Prof. Gillette— When plain sections and ordinary sections are stacked up separately, the plain sections take the eye better.

Mr. Adams— Don't we have to cater to the eye more than to the palate?

Prof. Gillette— Yes.

A. L. Foster— I am starting in the bee-business in Colorado, and I want to start right, not change after starting.

F. L. Thompson— Last season I had one-half of five supers full of plain sections with fences, and the other half of ordinary sections with plain separators. The plain sections did not prove superior to the others in the matter of filling at the edges of the combs, except in one super, and then it was but faintly apparent. On counting the number of holes through the combs next to the wood, I found that the plain sections averaged $2\frac{1}{2}$ holes to the section, while the ordinary sections averaged $3\frac{1}{2}$ holes. But this superiority of the plain sections was about all on paper, because I did not suspect it from the appearance alone, and only found it out by counting and computing. Of course, the combs were plump in comparison to the width of the section. I found they did not need separators in the shipping-case, as had been supposed they would. As I did not use special cases, but the ordinary ones, together with a follower and wedge, I cannot speak of the difficulty of withdrawing them from the case.

Prof. Gillette— I also found a small difference in favor of the plain sections, in the matter of holes in the combs. I have not the figures, but my recollection is, the percentage was identical with that mentioned by the last speaker.

S. M. Carlzen— Why does Mr. Honnett recommend the 8-frame hive to beginners? My hives had 15 frames of brood in them.

Mr. Honnett— I have 8-frame hives because I am troubled with the rheumatism.

Mr. Foster— I have a number of 8-frame hives, which I will use, tiering up if necessary. My brother, Oliver Foster, who runs for extracted honey, has 10-frame hives, which he tiers up sometimes five high, with brood in all of them.

H. Rauchfuss— Would you advise giving the queen access to the extracting-supers? I would not advise extracting from combs containing brood. There will be some thin honey, because thin honey is placed next the brood. I would confine the queen to one story, and use 10-frame hives.

F. Rauchfuss— The prevalence of 8-frame hives in Colorado is not due to the choice of the bee-keepers, but to that of the manufacturers. The 8-frame hive is easy to manage. Those who started manufacturing here advocated the 8-frame hive. Being bee-keepers also, their judgment was largely followed. Then Root's catalog advises beginners to use the 8-frame hive. There are many who would be glad to use the 10-frame, but they still continue buying the 8-frame because they wish to avoid a change. If the matter was left to bee-keepers, there would be an equal or greater number of larger hives used. One can produce just as much honey with the 8-frame hive, but it takes more labor, and therefore costs more.

[Continued next week.]

The Premiums offered on page 30 are well worth working for. Look at them.

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[Questions may be mailed to the Bee Journal, or to Dr. Miller direct.]

Granulation of Extracted Honey.

A correspondent informs me that I am in error in saying that all honey in the North will granulate when cold weather comes, if it is pure extracted. He says that in Gage Co., Neb., it is the exception and not the rule when extracted honey granulates before March. The honey is heart's-ease, of good flavor, not weighing more than 12 pounds per gallon.

I am glad to make this correction, and wish others would make it known if there are other localities in the North where extracted honey remains liquid. It is something new to me. C. C. MILLER.

Moving Bees Long Distances.

1. How many miles can bees be moved on a spring wagon? I expect to move about 200 miles or more in the spring. Is it best to move them by freight or express?

2. Is there air enough for the bees through the hive-entrance in moving? MINNESOTA.

ANSWERS.— 1. There is no limit to the distance bees can be hauled on a wagon, providing you stop each day early enough for them to have a little flight before dark, closing them up after all have gone in. They could be placed on a rack with the entrances facing outward, so they would not need to be taken off the wagon. It might be better to ship on the cars, especially if wagon-roads are rough, but the matter of cost must be considered.

2. That depends on the size of entrance and the weather. If cool weather, an ordinary entrance will be enough. If the temperature is up to 70 degrees or more, it would be better to have an entrance the full width of the hive and $1\frac{1}{2}$ to 2 inches deep; or, still better, wire-cloth covering the whole of the hive.

Worms Stripping Basswood Trees.

The basswood and other trees of this locality for the past two years have been stripped of their leaves and blossoms by a worm resembling the apple-tree worm. We have had no honey from basswood in the past two years. Can you tell me if this worm has come to stay? If so, will it kill the trees? NEW YORK.

ANSWER.— I cannot speak with any degree of authority, but give it as my opinion that the worm you speak of—if it is the same one I've seen in this locality—will not be a sufficiently continuous stayer to do any permanent damage to the trees. But I may be entirely wrong.

The Dadant Bottom Frame-Spacer.

I wish to thank A. P. Raymond for his article on frame-spacing, on page 738 (1898.) He mentioned a bottom-spacer described in Langstroth Revised, but does not describe it, and says some object to it because it is old. I would like it fully explained. OHIO.

ANSWER.— The bottom frame-spacer in Langstroth Revised has no description given, only a picture of it. You can make it somewhat after this fashion: Drive into a board a row of nails as far apart as the distance you want your frames spaced from center to center, that is, the nails will be $1\frac{3}{8}$ from each other if you desire to space your frames $1\frac{3}{8}$ inches from center to center. These nails are not to be driven in tight, but left projecting enough to hold the wire. A second row of nails is driven parallel to the first row, the two rows being something like two inches apart. In this second row, however, there are twice as many nails as in the first row, and they are arranged differently. Opposite the space between two nails in the first row are two nails about as far apart as the width of your bottom-bar. They are just far enough apart so that when the wire is bent

around them the bottom-bar will fit nicely into the bent wire. Now start to bend your wire by bending it around the first nail in the first row, then around not one nail but around the pair of nails in the second row, then around another nail in the first row, then around another pair in the second row, and so on. That makes your spacing-wire complete, but you can't get it off the board. You may draw the nails, or you may burn up the board. Neither way is as good as the plan of Mr. Dadant. Instead of having the rows of nails in the same board, he has them in two boards, the two boards being held apart by a piece at each end perhaps $\frac{3}{4}$ -inch in thickness. When the wire is properly bent, these pieces at the ends are drawn out, and the wire is easily removed. It is only fair to say that many bee-keepers nowadays prefer that the spacing shall all be independent of the hive and only connected with the frame. Mr. Raymond likes the plan of spacing he has described, and says: "I believe this method has several advantages over the staple or nail methods of spacing." Others think just the reverse. I had years ago hives with practically the same spacing he describes, and very much prefer spacing with nails or staples as I have described on page 791 (1891.) But every one has a right to his own preference.

Sections with and Without Separators—Questions on the Honey Crop.

1. Do you prefer using sections 1 $\frac{1}{2}$ wide, with separators? Or could you do about as well by using sections 7-to-the-foot without separators?
2. Did you ever harvest a good crop of honey from white clover the season following a dry freeze-up? Or did you ever know of any one that did, where irrigation was used?
3. Did you ever fail to secure a crop from white clover the season following a wet freeze-up? That is, the ground wet two feet or so before it froze? IOWA.

ANSWERS.—1. I can't do as well with either without as with separators. Some report that they can get along very well without separators, having very few sections that will not pack well in a shipping-case. It is likely that localities and seasons may make a difference. If honey comes in a flood from the time bees commence in a super till the sections are sealed, and if the colony is strong, separators are not so necessary. But if you think 1 $\frac{1}{2}$ are all right when separators are used, you should not think of using sections as wide as 7-to-the-foot; 1 $\frac{1}{8}$ without separators will give you combs of the same thickness as 1 $\frac{1}{2}$ with separators. If I thought of doing without separators, I'm not sure but I would use 1 $\frac{1}{2}$ -inch sections.

2 and 3. I've never kept track close enough to be able to answer. I'll be glad to yield the floor to any one who will answer. The questions are very suggestive.

Cutting Out Drone-Comb—Cleansing Flight—Sowing Alfalfa.

My apiary consists of 104 colonies, in double-walled Quinby hives.

1. How early in the spring should drone-comb be cut out of frames?
2. (a) In the spring should weak colonies be given frames of honey and brood from the strong ones? (b) If so, how early may it be done?
3. My bees came out yesterday (Dec. 29), as it was warm, and they covered the windows with spots which I had to wash off, and found it a rather hard job. Have my bees the dysentery?
4. My father has about a quarter of an acre of land in which he said I could plant Alfalfa next spring if I wanted to try it. Would you advise me to do so?

SOUTHERN ILLINOIS.

ANSWERS.—1. In time of fruit-bloom, or any time earlier on a day warm enough for bees to fly freely. But remember that if you cut out drone-comb and leave the bees to fill up the vacancy at their own sweet wills, they will be likely to fill up with drone-comb. The safe way is to fill up the holes with pieces of worker-comb. If you have say six frames containing more or less drone-comb, cut up one or two of them to provide worker-comb patches for the rest.

2. (a) It may do to take frames of honey from those that can spare them, and give to those that are needy, but as a rule you lose more than you gain to take brood from the strong and give to the weak, unless you wait till some are

very strong. (b) The honey may be taken at any time when the weather is warm enough for bees to fly freely, but no brood should be taken till the hive is pretty well filled with brood.

3. Probably not. It was only a cleansing flight.

4. I don't believe it will pay you, so far as the bees are concerned. I have known of some successful fields of Alfalfa raised in Illinois, but have never yet heard of bees getting nectar from them. Sweet clover would be more to the point.

Michigan Laws on Bee-Keeping The Union.

1. What are the rules or laws for keeping bees inside the corporation of city, town or village in Michigan? How many feet or rods from the public highway or adjoining property?
2. How does the United States Bee-Keepers' Union help new bee-keepers?
3. Does it assist him in selling honey? or is it like a good many other unions, only for the name of belonging to the union, and a help to those who have already got a market establishit for their product? MICHIGAN.

ANSWERS.—1. That's hardly a question for this department. You can find out a good deal easier than I can what are the laws of the corporation in which you live. Remember there are many thousands of cities, towns and villages, and it would take a lifetime to learn about all of them.

2. One way in which great good has been done is in defending those who have been persecuted by petty, unjust laws trying to drive them out of village or city corporations. In fact, it is much like an insurance company in that respect. But you can't get insurance on a house after it is burned down. Neither can you get help from the Bee-Keepers' Union unless you are a member *before* you get in sight of trouble. Of course, that's not the only good that comes from the Union. Among other things it has in view putting down adulteration, which will help all bee-keepers greatly.

3. I don't know of anything that will help the sale of honey more than putting down adulteration. I don't think many of us would pay in dollars merely for the name.

Getting Sections Entirely Filled.

I use the 4 $\frac{1}{2}$ x 4 $\frac{1}{2}$ sections with separators, and the bees do not fill the sections full, but leave holes at all four corners. How can I get the bees to fill them out?

ALABAMA.

ANSWER.—If you can find a way to have all sections filled out plump at the corners and get it patented, you have a small fortune in sight. Having colonies very strong will help toward it. Crowding the bees for room rather than allowing an excess of room is also favorable. It is claimed that the fence separators do not leave the corners of the sections as open as the plain separators.

York's Honey Almanac is a neat little 32-page pamphlet especially gotten up with a view to create a demand for honey among should-be consumers. Aside from the Almanac pages, the forepart of the pamphlet was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample for a stamp; 25 copies for 40 cents; 50 for 60 cents; 100 for \$1.00; 250 for \$2.25; 500 for \$4.00. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last. Better order at once, if you want a copy of this song.

GEORGE W. YORK, Editor.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY,

118 Michigan St., Chicago, Ill.

ONE DOLLAR A YEAR. SAMPLE COPY FREE.

[Entered at the Post-Office at Chicago as Second-Class Mail Matter.]

United States Bee-Keepers' Union.

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee \$1.00 per Annum.

EXECUTIVE COMMITTEE: Pres., E. Whitcomb; Vice-Pres., C. A. Hatch; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS: E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadaud; W. Z. Hutchinson; Dr. C. C. Miller.

GEN'L MANAGER AND TREASURER - Eugene Scott, Forest City, Iowa.

VOL. 39. JANUARY 19, 1899. NO. 3.

NOTE - The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England: - Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

A Big Cuban Honey-Crop is that of Dr. Vieta, as reported in Gleanings by W. W. Somerford. It was 360,000 pounds from two apiaries. That's all!

Apis Dorsata is strongly championed by the American Bee-Keeper. Since those who oppose it say that it cannot prosper in this land, why need there be any feeling about its introduction?

The Omaha Convention Report ran through 14 numbers of the Bee Journal, beginning with the first number in October, 1898. Now we have on hand quite a number of complete sets of that report, which we will mail for just 10 cents each. That is, 14 copies of the American Bee Journal for only a dime. There are doubtless a good many of our new readers who will be glad to get that fine report.

Kind of Bee-Keepers Who Succeed. Mr. L. B. Smith, in the Southland Queen, tells in one paragraph how to succeed in bee-keeping. Here is the method:

"You must read, study, and even dream about bees if you expect to make a good bee-keeper. You might succeed after a fashion without the bee papers and books, but failure is sure to come sooner or later. I cannot call to mind one man or woman that was in the bee-business 10 years ago that did not take and read the bee papers and books that to-day has any bees, let alone make any money out of it; while those that had taken and read books and journals have almost all had fair success, and some making good money at it."

Condition of Bee-Keeping in Cuba.—Mr. W. W. Somerford, has just returned from Cuba, where he took "a sort of inventory trip, to ascertain what was left, after the war, of some of the finest apiaries in the world, and also to embark in the bee-business again in Cuba after an absence of four years from that island." Here is what he reported in Gleanings:

"I visited many apiaries that were in a run-down condition. By way of caution I will suggest to those in a hurry to embark in the honey-business in Cuba, that there's plenty of time: the island is not such a paradise just now—not even for the modern honey-producer.

"And to those bee-keepers in the United States who fear that the American market is going to be ruined by cheap, dark grades of honey from Cuba, I will say that Amsterdam, Holland, and foreign cities in general, get the honey that's produced in Cuba—not the American markets. The American honey-producers in Cuba, who have tried the United States markets, have paid for their experience in shipping, commission, lighterage, freight, cooerage, drayage (import duty 10 cents per gallon), and commission, to say nothing of leakage; and by the time these charges are figured up, and the cost of package added, at the Cuban cost, 5 cents per gallon, the shipper wonders why he didn't sell in Havana at 40 or 50 cents per gallon net (packages paid for by the honey-buyer).

"After traveling hundreds of miles over the country I came to the conclusion that next October or November will be soon enough for the would-be Cuban bee-keepers to embark for Cuba."

The Dot Diagram Contest.—Last week we announced that this week we would give the result of the dot contest which ended Jan. 1. It will be remembered that we made four cash offers, and 60 Globe bee-veils, which retail at \$1.00 each. The cash offers were, 1st, \$50; 2nd, \$25; 3rd, \$10; and 4th, \$5. This makes a total of \$150.

There were 2083 dots in the diagram, and 84 persons who found that number are as follows:

Those Winning the \$50 Offer.

- F. McBride, John Peters, G. A. McDonald, S. S. Sampson, F. Mittermeyer, P. D. Wynn, Geo. W. Gross, R. P. Sweet, P. F. Schraut, M. Walrath, D. J. Troyer, R. Hurlburt, N. S. Cushing Jr, Arnold S. Reeves, D. A. Holman, John D. Gray, Geo. Crowden, Luke Nordhoff, J. W. Shirley, Mrs. L. Mack, R. B. Wheeler, B. W. Peck, John K. Kumble, John Scherer, A. E. Connor, John Stroebel, Jr, S. G. Jackson, L. M. Adams, John Michaels, W. H. Pridden, L. L. Skaggs, Joe Amman, W. L. Hunker, W. H. Wetherbee, H. E. Abbott, F. Greiner, H. F. Schultz, M. D. Andes, N. Richardson, E. D. Lerch, James W. Brown, F. W. Brown, L. A. Sverud, Frank J. Clark, A. H. Dean, Kelsey Hart, Wm. F. Ware, G. C. Britton, K. Hearing, Milo B. Brand, Oliver Adcock, Chas. Putman, John F. Beatty, G. W. Powell, R. A. McPherson, H. E. McGregor, V. N. Allen, R. Rodenberger, Roderick Cameron, C. A. Haines, M. B. Cooper, Geo. A. Cobb, B. C. Biegelow, O. Taylor, Rev. W. Knuf, John F. Logsdon, E. E. Allen, Wm. Irwin, A. P. Bender, A. M. Fisk, Lewis Sampson, Omer M. Smith, T. Pierpont, Jr, L. L. Moore, W. H. Price, Geo. J. Ward, E. V. Truesdell, R. Lowy, Otto A. Miller, G. S. Crego, Wm. Schopke, B. K. Lawton, A. F. Eickinger, L. J. Whitney

The next nearest counts were 2082 and 2084, and there were 125 who came under those numbers:

Those Winning the \$25 Offer.

- E. W. Lanier, Paul F. Bratz, Fred G. Berner, Alonzo Knights, G. L. Good, E. August Weiss, S. M. Cox, N. H. Vogt, John Morton, Fred Reitman, Mrs. M. A. Golden, John R. Anderson, A. J. Fisher, W. E. Virgin, J. W. Lane, John L. Walthor, W. Bishop, H. L. Meyer, W. H. Frisbee, C. A. Goodman, E. A. Snyder, Frank Fishell, S. H. Hurst, J. M. Urban, W. T. Sherman, G. J. Duane, L. Hansen & Sons, J. D. Moffett, A. Pontious, Jos. J. Giger, Wm. Wilson, Edmund Worthen, H. M. Rood, G. A. C. Clarke, H. J. Dayholl, G. W. Lawson, B. H. Volkering, John G. Krasser, Stephen Lawson, D. Cooley, H. L. Gloege, E. M. Peterson, Geo. Hallman, Orville Jones, Thos. S. Wallace, Philip Roth, A. C. Abbott, A. I. Cook, H. Sonnedecker, S. Burton, Jesse Willis, John J. Vonke, Allen Lewton, D. L. Carlton, E. G. Money, W. T. Henry, G. F. Hudder, L. P. Spring, E. Davison, J. J. Burke, Chas. W. Ingalls, John Kramer, J. B. Pyle, D. F. Berry, John Mott, M. S. Snow, Neil Gubraith, F. W. Haynes, W. R. Heintzelman, E. Mamecke, H. S. Norecross, F. C. Wiggins, Wm. Witkarsky, O. M. Pierson, Edw. Scoggin, H. D. Hill, Louis Thill, Thos. C. Stewart, T. W. McGinley, John T. Young, Chris Hedder, P. J. Green, Frank Snyder, L. P. Ballings, B. M. Snyder, E. A. Lundquist, Stoughton Cooley, S. Rudeman, G. F. Hudder, L. P. Spring, E. Davison, J. J. Burke, Chas. W. Ingalls, John Kramer, J. B. Pyle, H. H. Lampert, J. P. Blunk, Geo. W. Riker, Julius Herman, Geo. E. Nichols, J. J. Frantz, W. S. Benton, F. Sauter, Miletus Sims, Chas. Paul, A. T. Smith, Frank E. Ryerse, S. S. Butts, Percival Golden, Wm. Stewart, H. S. Jones, J. C. Hendricks, Geo. F. Fall, G. D. French, C. H. Eastman, C. C. Pastman, H. Nootnagle, John V. Emmert, M. S. Patterson, Geo. H. Weaver, Will Prindle, F. H. Krauss, George Weiss, G. E. Quimby

Next would be 2081 and 2085, and the following 103 reported these numbers:

Those Winning the \$10 Offer.

- Albert E. Isaac, S. H. Stouffer, Jno. D. Brown, C. F. Kaufman, V. W. McNeil, Alfred E. Smith, W. N. Harter, G. W. Wuxco, George C. Hall, A. Waddington, D. H. Croy, Aug. Weiss, J. O. Kvambeck, H. Hollis Pullen, H. Lammiman, Am. J. Healey, A. N. Draper, J. A. Dunn, M. McKinnane, H. E. Bradford, B. A. Smith, A. Shaw, J. A. Duncan, L. Staehelhausen, Wm. Helphrey, L. H. E. Trester, Wm. Munch, C. W. Brenner, J. H. Tait, B. C. Miller, J. W. Klein, E. H. Bridenstine, F. A. Crowell, Jas. Woodworth, A. Ziegler, James McNeill, R. J. Purrell, H. Trout, Fred Lehrens, C. J. Siffler, Henry Wilson, John Hopkins, E. H. Walker, Chas. Fowles, J. A. Tidmore, John Hildeman, S. M. Brandon, Wm. Russell, F. E. Smith, Andrew Vorum, J. F. Merrill, W. I. Copeland, C. Lindholm, Jno. M. Hanzeker, C. H. Carpenter, Geo. M. Sowardy, Alex. Rose, Chas. C. Current, Geo. D. Hecox, Rev. Chas. Horack, J. P. Puckin, F. Schach, N. Stammer, W. H. Cook, B. A. Armor, W. Math, H. Gibson, L. C. Preyer, W. E. Owen, Ernest W. Doe, L. B. Boardman, A. C. Paulker, A. S. Slemann, J. A. Munroe, Frank Lockhart, N. Roghair, John A. Pease, P. G. Bratten, Wm. Kichart, Jos. Fortier, E. C. Murphree, Geo. J. Stray, G. E. Sutherland, W. E. Tarbox, W. B. Morrow, Aaron S. Johnson, Wm. Rohrig, John Kidney, L. C. George, Fred Welty, Jos. Stephenson, F. Tambourine, S. M. Burns, E. John Rogers, Geo. I. Whitehead, E. J. B. Davenport, L. C. Purvis, John C. Ward, C. V. Mann, F. W. Unger, S. C. Kocourek, J. L. Terrell

The last of the cash winners are these 94, who reported 2080 and 2086 as the number of dots:

Those Winning the \$5.00 Offer.

- L. Morningstar, Thos. Dougherty, Jos. Kuhles, Willie Peterson, F. A. Chandler, E. Woodall, E. W. Brown, Paul Stahmer, Levi Moss, N. B. Franklin, F. Mothershead, Alina Wallace, W. M. Barnes, J. B. Ausmus, Fred D. Gibbins, Payne Bros, C. B. Howard, Edward Tanner, Wm. Webb, W. H. Dougherty, Hubert Fuchsen, Artie B. Fritz, J. A. Funk, W. H. Coe, Henry B. Pratt, B. H. Cross, C. H. Benson, Emile Belli, Jos. Unterbrink, F. M. Curtice, Geo. W. Ebling, G. W. Olds, Harry Brokaw, E. G. Sieber, Josiah Gately, L. G. Clark, A. R. Cowan, G. L. Hewitt, Wm. H. Daniel, Miss G. T. Love, O. B. Montfort, Wm. Goodler, Wm. G. Corey, G. Schermerhorn, H. W. Roop, D. Pullen, Wm. Price, Max Zahner, M. A. Foster, Geo. M. Buek, Wm. Renne, Jno. W. Lyell, S. D. McGinn, R. F. Jones, Mrs. I. D. Harrison, Frank L. Goss, F. W. Goodell, M. E. Hathaway, W. B. McGraw, J. P. Morgan, sr., Jas. Quinn, N. Staple, Geo. B. Schoff, W. D. Furry, J. J. Angus, Jos. Ostraduk, C. G. Burgess, A. A. Lepper, W. H. Bristol, Jos. Nondorf, H. C. Roberts, Daniel Wyss, S. A. Dickson, B. Weber, O. R. Coe, Geo. E. Dudley, Frank Coverdale, M. M. Stontler, Wm. N. Sessions, Mrs. John Moore, Chas. A. Gile, H. Wilkon, Jas. A. Stone, E. Woodmusee, Geo. A. Benner, H. W. Savage, N. P. Parsons, Robt. Kutzner, Jac. Verret, Edw. Craig, E. L. Hayes, H. C. Day, W. S. Stansell, C. V. Tomlinson

The 60 who are entitled to bee-veils are the following, with either 2079 or 2087 dots, the veils having been mailed:

Those Winning the Bee-Veil Offer.

- Geo. Randall, Marcus N. Ames, I. N. Jacoby, Geo. Welter, jr, Theo. Rehorst, H. E. Truesdale, E. Webb, W. S. Feedback, J. H. Stock, H. M. Arndt, Edwin Crowell, D. P. Ott, Malcolm Fairchild, D. P. Stevenson, J. L. Ballow, W. L. Kemp, A. Wurfel, W. T. Collins, F. W. Galway, W. F. Justin, Henry Withereil, James Shearer, A. Rozell, G. W. Petrie, R. R. Ryan, A. G. Butler, W. A. J. Simpson, Jos. H. Cox, Mrs. D. E. Graves, E. Nuckols, Peter Galle, H. Braun, Fred Robey, Chas. King, Mrs. Mary Haas, C. S. Cochran, Mrs. F. C. Bundy, W. H. Tuttle, Wm. H. Tripp, H. S. Pollock, N. Paulsen, E. M. Bradford, J. B. Sullivan, F. Grosser, Ernest Reid, E. M. Stocum, Willis Thompson, John F. Sautter, B. W. Hall, W. T. Suter, G. K. Hubbard, Chas. Karantz, H. M. Raboek, A. J. Howe, H. W. Best, H. R. Robertson, Elsie Markley, A. C. Tilden, C. O. Cornelius

As to the cash offers, we are ready to mail them at once, but have decided to suggest the following, which was thought of only last week:

All know that a Langstroth Monument Fund is being raised. Now every bee-keeper in the land will want to help on that fund. Why not those who are entitled to cash awards, just drop us a postal card instructing us to send to Mr. Secor what is due them, and let it apply on the Langstroth Monument Fund?

Those getting the \$50, are entitled to 60 cents each; the \$25 ones, 20 cents each; the \$10 ones, 10 cents each; the \$5 ones, 5 cents each.

There are 406 of the cash winners, which would cost us \$8.12 just for postage to mail them their amounts. Now we will add that two cents to each one's amount who will drop us a card telling us to send it to Mr. Secor for the Langstroth Monument Fund. You see, if all of the 406 would decide to do this, we would just mail Mr. Secor a check for \$98.12, which would be a handsome addition to the fund, and go far toward getting a fitting monument.

How about it, friends? Do you want us to do that? If so, please drop us a card at once. If not, we will mail what is due in February. Or, if you wish us to make any other disposition of the amount due you, please tell us promptly.

MR. D. D. DANIEL, a bee-keeper of Dane Co., Wis., was written up lately in the Wisconsin State Journal, at Madison. Mr. D. has 55 colonies of bees. He is the oldest bee-keeper in his part of the country. In 1879 he imported 12 Italian queens, for which he paid \$68.42.

THE DES MOINES INCUBATOR Co., of Des Moines, Iowa, has sent us their 5th annual catalog, showing their "Successful" henless hatchers. It takes 148 pages to tell about them, and they mail their catalog for only 6 cents. Better send for a copy, and tell them you saw their advertisement in the American Bee Journal.

THE KREUTZINGER ENTRANCE-CLOSER (page 35) we have examined, and, upon testing it on our hives, we find in it the merits which are mentioned. We understand that arrangements are being made to offer them for sale. The retail price will likely be 20 cents each. Any one desiring a sample, can send that amount for it to the office of the American Bee Journal.

THE RELIABLE INCUBATOR & BROODER Co., of Quincy, Ill., are a great concern. Not because they advertise in the American Bee Journal, but because of their success in making reliable goods for poultry-keepers. Their 1899 catalog, with its 228 pages, is mailed for 10 cents to any one interested. Send for it, and also mention having seen their name in this journal.

MR. G. M. DOOLITTLE, writing us Jan. 12, when sending an article for publication, said:

"Hardly able to do anything. This is the first article this year, action of heart is weakened, and extremities are like sticks. 'Tis almost painful to be using hands and feet that don't seem like mine."

But we are glad Mr. Doolittle is "on the mend," even if it is slow and painful. We hope soon to hear that he is all right again.

DR. C. C. MILLER, after taking time to "make up his mind," wrote us Jan. 11:

"The Bee Journal for the new year with its face washed, hair combed, and clean clothes, is a beauty. Those little vignettes between the articles in the first department are very neat. The more I look at the new type, the better I like it."

Thank you, Doctor. We thought you would be pleased with the "shining up" of the old American Bee Journal. We have long wanted to put a new "dress" on our paper, but couldn't well see our way clear to do it before. The old "dress" was worn just eight years, having been "fitted on" by Mr. Newman. Surely, a new one was well deserved.

CAPT. J. E. HETHERINGTON perhaps the largest honey-producer in all New York State wrote us Jan. 6:

"I have great faith in the United States Bee-keepers' Union if its present officers will stand by it with the good sense and energy they certainly possess."

Capt. Hetherington, who is one of the "old-timers" in bee-keeping, knew intimately the lamented Moses Quimby, who did so much to place practical bee-keeping upon a higher plane. We had the great pleasure of meeting the Captain at the Buffalo convention, in 1897, and there formed an exalted estimate of him and his work in apiculture. He delivered a most eloquent address at that meeting of the Union, going back over the many years of his apian experience, and paying high tribute to the labors and memory of Moses Quimby. We regretted exceedingly that no shorthand reporter was present to "take down" the Captain's interesting address, so that it might be preserved with the rest of the proceedings of that memorable Buffalo convention.

Properly-Reared Queens Give Best Results.—G. M. Doolittle says his queens now require a larger brood-nest than they did before he began rearing them according to the plans given in his book on "Scientific Queen-Rearing."—Gleanings.

His Honey Sells Itself.—S. F. Trego has been selling 15 pounds of nice heart's-ease extracted honey for a dollar, and now he does not need to seek for customers, with granulated sugar 16 pounds for a dollar—the honey just sells itself.—Gleanings.

Sealed Brood as Bait.—In order to induce the bees to commence promptly in the extracting-super, J. W. Rouse puts in the super a frame or two of brood, and he says the queen is less likely to go up if the brood is all sealed.—Progressive Bee-Keeper.

A Use for Propolis is given in Revue Internationale as a substitute for gum-lac in the manufacture of fire-works. Gleanings thinks no one would want to take the job of gathering 100 pounds of it at \$5.00 a pound. Perhaps propolis is not as plenty at Medina as at some other places.

Horse-Hair Veils, or those having the face part of that material, says F. L. Thompson, in Gleanings, are about equal to cotton tulle veils for seeing through, with the advantage that they never gather in folds. He has one in which the horse-hair part is still good after two seasons' use.

Cost of Large Hives.—C. P. Dadant, in comparing large with small hives, gave the cost of the large ones as about double as much as that of the small ones. In a later number of Gleanings he reconsiders the question, and gets figures from the A. J. Root Co., to the effect that the cost is only 40 to 50 percent more.

Clipping Queens seems to be quite popular in Canada. At the Ontario Convention nearly all seemed to be "clippers." Editor Holtermann met the objection that clipped queens are more promptly superseded by saying that unclipped queens are superseded without it being known. When a clipped queen is superseded, it can easily be known.—Canadian Bee Journal.

To Preserve Combs Against Bee-Moths.—A. Delcours puts them in a close place and then puts in a piece of rag saturated with essence of aspic. He prefers this to sulfur, as it avoids the danger of fire, and also because the sulfur does not affect the eggs, while the aspic either affects the eggs or else remains to affect the young larvae when they hatch out.—L'Abcille.

To Liquefy Honey.—An item from Gleanings advising to set glass packages of granulated honey in the oven of a cook-stove is being copied by other journals, but without adding the direction given in Gleanings to set the glass vessels in shipping-cases. A glass tumbler may be set on a shingle in the oven all right, but if set directly on the hot metal it will come to grief.

Value of Queens. In opposition to the views of Editor Hutchinson, who says queens are the least expensive part of a colony (making that an argument in favor of small colonies), C. P. Dadant, in Gleanings, is emphatic in the assertion that in the spring the queens are the part of most especial value. In the spring there is a lack of queens and an overplus of empty hives and combs.

Egg-Laying Depends on Kind of Honey. Doolittle having made the statement that nine Gallup frames would entertain the best queens to their fullest capacity as to egg-laying, and Dr. Gallup having said that a queen of his occupied fully 24 frames, Dr. Miller asked Doolittle in Gleanings how he reconciled the two statements. Doolittle replies that he was talking about colonies used for comb honey, while Gallup was talking about extracted. He says:

"There is something about extracted honey that causes bees to feed a queen in such a way that she will give double the eggs, if she has comb-room, that she will when no extracting is done." He says he gets no more brood in his 10-frame Langstroth hives than he does in his 9-frame Gallup hives (equivalent to 6 $\frac{1}{2}$ Langstroth frames.)

Drouth and Honey Crops Go Together in Texas.—The editor of the Southland Queen having reported that for lack of rain he was feeding his bees, G. F. Davidson says he thinks no one else is doing any feeding, and in an experience of 13 years he has had his best crops of honey when it was extremely dry, altho getting good crops when rain was plenty. No rain fell from Aug. 20, 1886, to May 9, 1887, and 1887 was the best honey-year he ever knew.

Burying Bees for Winter.—Jungelaus publishes, in Leipziger-Bztg., his experience therein. Nov. 14 he put his bees in a hole dug seven feet deep, lined with boards, covered with boards on timbers, then put roofing-paper over this, then 16 inches of earth, and over the whole a covering of roofing-paper weighted down with stones to prevent blowing away. After four months the bees came out in fine condition, the average consumption having been 3 $\frac{1}{2}$ pounds.

The Wedding-Flight of the Queen, says R. Wiesner, in Deutsche Imker, is supposed to take place as a rule only once, and at the most only five or six times, but he determined that in favorable weather, with plenty of drones, a queen takes at least 10 such flights, at about 11 o'clock, each flight lasting only a few seconds, and at the longest only 10 minutes. In 1895 a queen that returned to the hive with signs of mating took three flights on the following day, and did not begin to lay till the 8th day after the last flight.

Large Hives are advocated in Southland Queen by L. Stachelhausen. He says he has found by actual test that they are more profitable. Especially in seasons with not very good honey-flow, these strong colonies are sometimes the only ones that yield any surplus. Even if two weak colonies should store as much as one strong one, it takes more time and labor throughout the year to take care of the two weak ones. The two weak colonies will consume for their own use a good deal more honey in the course of the year than a single colony equal to their combined force.

Prevention of Swarming.—Last season Mr. Doolittle caged his queens in the out-apiary when the yield was on and there were signs of swarming. Ten days later the queen was removed and a young laying queen was put in the same cage, the cage being left in the same position in the hive. Enough candy was in the cage so the bees liberated the queen in about two days. This prevented all swarming, and left the colony with a vigorous queen for next spring's breeding. Of course all queen-cells were cut at the time the young queen was given.—Progressive Bee-Keeper.

Getting Wax Out of Combs is done by Wm. McNally after this manner: "Our wash-house boiler is of 25 gallons capacity, and into this I put 10 gallons of rainwater and three tablespoonfuls of vitriol; I then procure a clean, old, strong bag, like a very open sugar-bag; the combs are prest hard into it to a size that will go inside the boiler; it is then firmly tied, and immerst in the boiler of water. As the combs melt the wax oozes out and is laddled off the top and poured into clean, cold water. The vitriol and the pouring into cold water improves the color. A second melting of the wax is necessary to put it into marketable shape.—Bee-Keepers' Record.

Death from Stings. Geo. L. Vinal gives in Gleanings a detailed account of the case of a horse that received many stings on head, nose, ears, neck and body. The normal pulse of a horse is 36 to 40 in a minute; respiration, 10 to 12; temperature, 98.3-5. In 45 minutes the pulse was 60, respiration 30, temperature 102. Urine highly brown color, with frequent watery evacuation of the bowels. 15 minutes later pulse was 80, respiration 60, temperature 104, the horse throwing himself down, jumping up, plunging and tugging at his rope, and whinnying in a loud, shrill voice. 75 minutes later the symptoms began to abate, the breathing becoming heavy, the extremities showing paralysis, and four hours after being stung he was no longer able to get up, and seven hours after being stung he died.

Root's Column

We are not quite ready yet to tell you about our new goods and some of the improvements we have made in certain lines; but when we are, we propose to tell you something that will interest you beyond a doubt; so

KEEP YOUR EYES ON THIS COLUMN

While our engravers are busy finishing certain cuts, we desire to call your attention to

Gleanings in Bee-Culture.

If you haven't seen late numbers, send for sample copies. Among other things you will discover that it is

An Illustrated Bee Journal.

If you are a busy man, and haven't time or inclination to read much, you may pick up in Gleanings an idea that will be worth dollars by once glancing at a cut.

During the coming year we propose to describe several different manipulations pertaining to bee-keeping, by a series of line cuts that will show you just how it is done.

Another Big Offer.

In addition to our other offers in last week's Bee Journal we propose to make one more.

Queen-Bee Free.

To every one, either an old or new subscriber, sending us \$1.00 for Gleanings for one year, we will send, some time in July or August next, one UNTESTED ITALIAN QUEEN.

CONDITIONS:

Old subscribers may take advantage of this offer, providing that all back dues on subscription, if any, be paid at the rate of \$1.00 per year in addition to \$1.00 in ADVANCE for Gleanings and the queen. We reserve the right to send queens in July or August in the order that these subscriptions are received. First come, first served. Again, as we are giving these queens away free we cannot guarantee replacing in case one dies in the mails. We will use our best mailing-cage, and take every precaution, but cannot do more. So far as possible queens will be reared in our own yards by the Doolittle method; but if the demand for these queens is too great we reserve the right to order from reliable breeders to help out. First orders received will probably take queens of our own rearing.

Remember that the \$1.00 secures a year's subscription to Gleanings and an Untested Italian Queen, providing that all arrears, if any, are paid. Send all orders to

The A. I. Root Company
MEDINA, OHIO.

In the multitude of counsellors there is safety.—Prov. 11-14.

How to Win Success in the Honey-Selling Business.

Query 88. I am a young man desiring to build up a demand for both comb and extracted honey, with the view of following honey-selling as a business. Briefly, what would you advise that would tend to success in the line indicated? City.

- E. France—Honesty and push.
- Rev. M. Mabin—The question is too big for this department.
- W. G. Larrabee—Always have a first-class unadulterated article.
- Prof. A. J. Cook—Energy and honesty. They will win, SURE.
- C. H. Dibbern—Get out and hustle, and don't be afraid of any one.
- G. M. Doolittle—That you supply your customers with only the best.
- O. O. Poppleton—I have had too little experience in this line to offer advice.

J. A. Green—Sell only good honey, at a price that will pay you for your labor.

Jas. A. Stone—Deliver true to sample; give honest weights, and live up to contract.

P. H. Elwood—I haven't had much retail experience. Produce a good article, and distribute honey-leaflets.

J. M. Hambaugh—Handle the pure stuff, put up in attractive and durable shapes, and advertise, and work.

Dr. J. P. H. Brown—Read the articles on marketing honey in late numbers of the American Bee Journal.

Mrs. L. Harrison—Representing goods just as they are. Buy or sell no faced goods; do an honest business.

Chas. Dadant & Son—Take samples and sell from these in all sizes of packages. A quick mind and a glib tongue are useful.

Eugene Secor—I advise the same methods that make success in any other line of business—integrity, energy, perseverance.

Emerson T. Abbott—Attend strictly to business; do not talk politics or religion; handle only first-class goods; deal fairly; and stick to it.

E. S. Lovesy—Honesty is the best policy. Try to carry the best goods, and give the producer and consumer a square deal, and your success will be assured.

A. F. Brown—Get started, and keep at it, advertising your business, never tiring of setting forth the merits of honey as an article of food. Briefly, PUSH is the word.

R. L. Taylor—Learn to know the quality of honey, how to handle and take care of it, and the tastes of your customers. Deal fairly, be active and indomitably persistent.

S. T. Pettit—Be candid, punctual, prompt and obliging, but not subservient. Keep your place of business very clean. Handle nothing but pure

goods. Display your goods in a way to make them attractive. Manifest a cheerful willingness to wait upon people, but don't urge them to buy, and they will buy again.

D. W. Heise—Read up, and put into practice the able articles written by H. F. Moore in the American Bee Journal, on "A B C of Marketing Honey." I know of nothing better.

R. C. Aikin—Honesty, fairness, firmness, frankness, push, advertising, "always and everlastingly at it." Have good goods, and have them all the time, and get the people to using them.

J. E. Pond—Learn to keep bees and care for them. Offer your honey honestly to the public, giving just what is wanted. Never offer an inferior article for a good one, and generally follow the Golden Rule.

Dr. C. C. Miller—Utter and entire honesty; familiarity with the markets and with the methods of producing honey. Read all the articles that have been written in this and perhaps other journals on the subject.

G. W. Demaree—In my opinion, to be or to become a successful honey merchant, one must be an apiarist. He should know how to produce honey. And he should do business in a way to gain the confidence of all with whom he has dealing. *Straight* is the word.

Dr. A. B. Mason—Read the articles by Messrs. G. K. Hubbard and Herman F. Moore that have appeared in the American Bee Journal during the past year, and make use of the information so obtained; and don't overlook what Mr. Moore says about section-cleaners on page 595 (1898).

Bees in Fair Winter Condition.

Bees did well last spring. I increased from 11 colonies to 32, by natural swarming, and obtained 400 pounds of comb honey. The latter part of the season was not very good, but bees are in fair condition for winter; one-half pack on the summer stands, and the rest in the cellar. I could not think of doing without the American Bee Journal.

GEO. SCHIERMEHORN,
St. Lawrence Co., N. Y., Dec. 20.

Honey-Dew and Fall Honey.

My apiary consists of 30 colonies in Langstroth hives, mostly Italians. I have taken about 900 pounds of comb honey, about half honey-dew, the balance fall honey. I had a swarm of Italians Sept. 27; after filling 21 two-pound sections they left me.

I am well pleased with the American Bee Journal, and can't do without it.

P. McDOWELL,
Mason Co., Ky., Dec. 20.

A Comb Honey Bee-Keeper.

Bees are wintering nicely up to date. They had a flight Dec. 18. I have 257 colonies in three different yards, packed in chaff hives. Last season I secured 5,000 pounds of comb honey from 198 colonies, and increased to 253. In my 20 years' experience with bees, last season was the poorest except one. In that time I have produced and sold 37 1/2 tons of comb honey. The last

SWEET CLOVER

And Several Other Clover Seeds.

FIFTEEN YEARS FOR A DOLLAR; ONE-HALF CENT FOR A MONTH.

Dear Sir:—Have used the Conqueror 15 years. I was always pleased with its workings, but thinking I would need a new one this summer, I write for a circular. I do not think the 4-inch Smoke Engine too large.

January 27, 1897. Truly, W. H. BAGERTY, Cuba, Kansas.

T. F. BINGHAM, Farwell, Michigan.

Bingham & Hetherington Uncapping-Knife.

BEST

EXTRACTED HONEY FOR SALE.

ALL IN 60-POUND TIN CANS.

ALFALFA HONEY.

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

BASSWOOD HONEY.

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms in Wisconsin. It has a stronger flavor than Alfalfa, and is greatly preferred by those who like a distinct flavor in their honey.

Prices of either Alfalfa or Basswood Honey:

A sample of either, by mail, 8 cents; samples of both, 15 cents (to pay for package and postage. By freight—one 60-pound can, 8 cents a pound; two cans, 7 1/2 cents per pound; four or more cans, 7 1/2 cents per pound. Cash must accompany each order. In ordering two or more cans you can have half of each kind of honey, if you so desire. This is all.

ABSOLUTELY PURE BEES' HONEY,

The finest of their kinds produced in this country.

We would suggest that those bee-keepers who did not produce any honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere. "YORK'S HONEY ALMANAC" will be a great help in creating customers for honey. See prices on another page.

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.

SAVE MONEY AND FEED BY BUYING AND USING OUR **\$5.00 FARMER'S FEED COOKERS**

It is low priced, not cheap. Made from the best of cast gray iron with 14 oz. galvanized steel boiler to hold 20 gals. Just the thing for cooking feed for stock, pigs or poultry and heat water for scalding hogs.

Reliable Stock Food Cookers are equally good but of much larger capacity, 25 to 100 gals. We will be glad to quote prices on inquiry. Do not buy until you get our free descriptive circulars. Better write for them at once.

RELIABLE INCUBATOR AND BROODER CO.
Box B2, Quincy, Illinois.

eight years I have sold it in Chicago. In my 20 years' experience in shipping honey to commission men in more than 12 different cities, I never had the pleasure of meeting an honest commission man till I met him in Chicago. Up to eight years I had the same opinion of commission men that the immortal Horace Greeley had of the Democrats. "He did not think all thieves were Democrats, but he thought all Democrats were thieves." C. D. DOANE.
Genesee Co., Mich., Dec. 22.

[We fear that "Horace" was pretty severe on the Democrats. We know some that are nice men. But we care more for the man than for any party name.—EDITOR.]

He Likes Bee-Keeping.

The Bee Journal has been a great help to me. My bees did well last summer. I like bee-keeping as long as I can have the Bee Journal as an adviser. FRED ROBY.
Hall Co., Neb., Dec. 17.

Wintering in a Cave.

The American Bee Journal has been a great help to me the past summer. I had bees on shares and could not have gotten along nearly so well without it. I got my dollar's worth (the price of a yearly subscription) out of several single numbers at several different times. I will not be without it as long as I keep bees and can raise the subscription price.

I put 94 colonies into the cave last fall, and they are all right so far.

T. J. BROOKS
Pine Co., Minn., Dec. 17.

Bees Did Fairly Well.

I began in the spring of 1898 with five colonies, and increased to nine, but I had one swarm issue Aug. 16, and another Aug. 22. In October I put the two together and gave them 15 pounds of honey in addition to what they had. My bees did fairly well the past season, and if I can succeed in getting them through the winter all right I shall be glad. J. W. HAWKINS.
Buncombe Co., N. C., Dec. 16.

A Beginner's Report.

I commenced the spring of 1898 with three fair colonies, and had nine good swarms, but I was unfortunate in losing one queen, so I doubled its colony with another. It worked all right, so now I have 11 colonies in the cellar, with a fine lot of honey in each hive.

We had a lot of fun catching swarms, and my wife thought not so much in watching for them to issue. It was not a very good season for honey, but what we got in the supers was No. 1—the best I ever saw. Next year I hope for a better season and more honey.

I like the American Bee Journal; it is a great help to me, and I will continue to take it as long as it helps me so much.

M. N. AMES.
Vernon Co., Wis., Dec. 19.

An Old Bee-Keeper's Report.

I am nearing 81 years of age. I put my bees out last spring, and when they were ready to go to work there were about 75 or 80 colonies, which increased to about 100, and I got about 30 pounds of surplus honey, not all marketable. They had stored for winter from 30 pounds down to starvation. I thought I would try to winter the greater part, so I bought a big barrel of sugar and fed them. I got ready to put a part of them into the cellar, and a part pack on the summer stands. I got up on a Monday morning, and the ground was covered with sleet and snow. The next morning, Nov. 22, the awful snowstorm came, and there the bees are under the snow, and there they are likely to stay while they live.

HIGH-GRADE INCUBATORS
 WE CAN SUIT YOU IN PRICE AND WE GUARANTEE TO PLEASE YOU IN QUALITY.
 What more could we do? Our catalogue tells all, and is devoted largely to practical matters pertaining to poultry raising. Has 138 pages; mailed to any address for 6c. No wild and woolly statements, toy outfits, nor prize package lots to offer. Fair treatment, prompt service and full value are what we try to give our customers.
DES MOINES INCUBATOR CO. Box 78, Des Moines, Iowa.

Page & Lyon Mfg. Co.

NEW LONDON, WIS.,

Operates two Sawmills that cut, annually, eight million feet of lumber, thus securing the best lumber at the lowest price for the manufacture of **Bee-Keepers' Supplies**,

They have also one of the **LARGEST FACTORIES** and the latest and most improved machinery for the manufacture of **Bee-Hives, Sections, &c.**, that there is in the State. The material is cut from patterns, by machinery, and is absolutely accurate. For Sections, the **clearest and whitest Basswood** is used, and they are polished on both sides. Nearness to Pine and Basswood forests, and possession of mills and factory equipment with best machinery, all combine to enable this firm to furnish the **BEST GOODS AT THE LOWEST PRICES.**

1898 **AUGUST WEISS, Hortonville, Wis.**

MAMMOTH OFFER.

For only 25 cents -I will mail you -on receipt of this amount **Four Valuable Money-Making Secrets. ELECTRIC POWDERS** one of the most salable articles of the day and as staple as flour; something that every house-keeper will buy. It is useful for gold and silver, brass, copper, tin, steel, or any material where a brilliant lustre is required.

Farmers' Paint Farmers will find this profitable for house, fence, or bee-hives.

Grafting-Wax The best kind that is made; it has no equal.

Washing Powder the Laundress' Assistant. Warranted not to injure the finest fabric. No acid, no potash. In the wash-room it saves time, labor, expense, muscle, temper, and hands. The clothes will come out clean and white without wear or tear, or rubbing on washboards; therefore will last twice as long. It also requires to be tested to be appreciated. It does not give satisfaction I will refund the money. All these total value \$2.00 all for 25 cents, stamps or silver. Address quick, JOHN GASSON, Brock, Darke Co., Ohio. 3A11

TWO WAGONS AT ONE PRICE.

It is a matter of great convenience and a saving of labor for a farmer to have a low, handy wagon. They save more than half the labor of loading in hauling manure, hay, grain, corn-fodder, wood, stones, etc. The man who already has a wagon may have one of these low

handy wagons at the small additional cost for a set of wheels. These Electric Steel Wheels, with either direct or stagger spokes, with broad-faced tire, are made to fit any axle. You can convert your old wagon to a low, handy wagon in a few moments. You thus virtually have two wagons at one price. Write to the Electric Wheel Co., Box 16, Quincy, Illinois, for their catalogue, which fully explains about these and their Electric Handy Wagons, Electric Feed Cookers, etc.

Please mention Bee Journal when writing.

Marshfield Manufacturing Company,

Please mention Bee Journal when writing.

MARSHFIELD, WISCONSIN.

That seems to be the only way I can get rid of them.

One thing I would like to say for encouragement of bee-keepers, and that is, if I am not a false prophet, 1899 will be a good honey year, for this reason: In 1897, about the middle of July, vegetation dried up, the clovers killed out, bees quit breeding; the bees that went into winter quarters were old field-bees. There was so much spring dwindling, and they were so late in getting to work; while in 1898 they kept breeding quite late, and the hives were full of young bees. More: The clovers are seeded thick, and we are having a good winter for it to keep.

Can't do without the Bee Journal, if my bees live.
 A. F. CROSBY.
 Franklin Co., Iowa, Dec. 21.

A Good Report.

I began the spring with 26 colonies, increased to 32, and ran 24 for honey. My total crop was 2,350 pounds. Six colonies were used for experimental purposes. My bees are all Adel, and I can assure you I have a strain for business. I crossed one with 3-banded Italians, and another with the golden strain. I would not exchange my hives for all other hives. I have a hive that has wintered bees for six years, without loss, on the summer stands.

C. VAN BLARICUM.
 Calhoun Co., Mich., Dec. 19.

Fears Overstocking.

There are a good many bees in this vicinity, and I am a little afraid it is overstocked. I think there are nine men owning bees within the city limits, and about four of these on quite a large scale. Then there are several within one or two miles of town. I am the only one that winters bees on the summer stands, but so far I have been very successful with this method.

Grant Co., Wis., Dec. 19. A. SHAW.

Wintered Without Any Bee-Bread.

I have 100 colonies of bees in the cellar, all in good condition. I got 3,000 pounds of comb honey the past year, mostly light. I have made some experiments with bees the past season; also wintered two colonies without any bee-bread at all, last winter.

I could not do without the American Bee Journal for twice what it costs.

ROBT. H. NORTMAN.
 Jackson Co., Wis., Dec. 18.

A Short Honey Crop.

I like the old American Bee Journal very much, and do not want to miss any of the copies as long as I keep bees. My bees are in good condition for winter, tho our honey crop was short this year—I got only about 2,500 pounds, which I sold at home, and could sell as much more if I had it. I had only 65 colonies to start with in the spring, and increased to 140. I hope next year will be a good one.

W. W. WILLIAMS.
 Goliad Co., Tex., Dec. 18.

Last Year a Hard One.

I am an old bee-keeper, having kept bees ever since I was old enough, except the four years during the war, 1861 to 1865. I have only 36 colonies at present. This year was a deadener in this locality.

S. POLAND.
 Richland Co., Ohio, Dec. 21.

Will Use 10-Frame Hives.

Last spring I got the bee-fever and then I commenced to read up on bees, and I got two colonies, one in an old soap-box, which I transferred, combs and all, into a St. Joe hive. It stored about 30 pounds of honey. I also transferred one for my neighbor which stored for him 25 pounds. Both did well, and went into winter quarters in good condition. I think I did well, not

having had any experience before, except what I learned from the book "Bees and Honey."

My other colony stored for me 75 pounds, and I now have four colonies in good condition.

I am using the St. Joe hive, 8 and 10 frame. I will use the 10-frame hive hereafter, as I think it is the best. I can have a larger colony in a hive that costs but a few cents more. Generally the larger the colony the more honey, and the less trouble.

N. H. VOGT.

Nemaha Co., Kan., Dec. 19.

Predicts Winter Loss of Bees.

Bees did very poorly the past season. From 38 colonies, spring count, I had only one swarm, and somewhere between 500 and 600 pounds of comb honey. I believe there will not be many bees in this locality by next spring. They have mostly honeydew stores for winter. Prospects are good for next season.

The American Bee Journal is what every bee-keeper needs. HARVEY BROKAW.
Richland Co., Ohio, Dec. 16.

Poor Season in 1898.

The past season was a poor one for honey in this county, but we hope for better things in the future. I must have the American Bee Journal as long as I handle bees.

W. H. TUTTLE.

Union Co., Iowa, Dec. 21.

Poor Season for Honey.

The past was a very poor season for honey. I have 19 colonies in the cellar in fair condition. I have plenty of honey for the home table, but none to spare as surplus.

W. H. KIZER.

Jasper Co., Iowa, Nov. 22.

Cheap Bees and Honey.

Comb honey is selling at 10 cents a pound here. Bees are in good condition, but beekeepers seem rather discouraged. Any one can buy all the bees he wants now for \$2.50 a colony. Two years ago they were \$5.00.

N. RICHARDSON.

Steele Co., Minn., Dec. 19.

Wintering Well.

Bees are wintering well so far. It is raining to-day.

W. M. DANIELS.

Wood Co., Ohio, Dec. 19.

Results of the Past Season.

My bees went into winter quarters in good condition. I have 31 colonies—4 in the cellar, and the balance outside in chaff hives. I had about 800 pounds of surplus honey this year from 31 colonies. Last year I had 2,000 pounds from 13 colonies.

M. BEST.

Lucas Co., Ohio, Dec. 18.

A Young Bee-Keeper.

Two years ago my father bought 4 colonies of bees, and the next year they increased to 9, and this year to 14. Now he has given them to me for full management. I am 16 years old, and take the greatest interest in bee-culture. I have read all the works on bees I could get hold of, and find nothing in the way of general information as good as I can find in the American Bee Journal.

WILLIE T. STEPHENSON.

Massac Co., Ill., Dec. 19.

Report for 1898.

Our summer flow from white clover was short on account of dry weather; about 30 pounds per colony, spring count, half comb and half extracted. My apiary is located on the beautiful Upper Iowa river, just over the State line on the Minnesota side. The bee-business has not been a success in

this section the past season, as the continuous dry weather absolutely dried up everything just as the hives were in the bloom, and I am sure that a great many beekeepers in this section will find before next June that their number of colonies will be greatly cut down, as brood-rearing stopt two months earlier than it should have been allowed to do if feeding had to be resorted to. Of course, all practical beekeepers feed enough to keep up brood-rearing sufficient to make sure of plenty of young bees for the winter, and those that did not will see it after it is too late.

F. A. CROWELL.

Fillmore Co., Minn., Dec. 20.

Very Short Honey-Flow.

I keep about 25 colonies almost for my own use. This year we had a very short honey-flow—only about 15 days. I had between 1,300 and 1,400 pounds of honey, mostly extracted. From one colony I got 162 pounds this year; last year I took 158 from the same hive. I think my bees did fairly well considering the short honey-flow. I have all Italian bees. I have tried to get the best I can find the past four or five years. I like the clear, bright 5-banded the best. I have some pretty nice bees. I have one queen I bought last spring for an extra-good one, and paid \$2.00 for her, and I would not give 25 cents for another unless I could not help it. I clipped all of my queens last spring, for I could not spend the time to watch them through the swarming season. When I thought the colony was nearly ready to swarm I caged the queen and then would go through in eight or nine days and cut the queen-cells out, and let the queen go. Sometimes I would take the queen away and let them rear a queen and cut the rest of the cells away. Either way works well.

I am well pleased with the American Bee Journal, and think it well worth the money invested.

J. W. McCALPIN.

Ontario, Canada, Dec. 19.

The Past Season's Report.

My report this year is: From spring count, 38 colonies, I have taken 1,000 pounds of honey. I build my hives two stories high, dovetailed bodies, and 8 frames each. I have not had a natural swarm from a two-story colony since I began using them, four years ago. My bees are Italians and hybrids. I leave 25 to 50 pounds of honey in the hive until spring, as it pays me better, and then no feeding, and I can sell the honey at better prices. I am a farmer, and make a regular hand in the field. I have a wife and four small boys to support.

E. C. MURPHREE.

Blount Co., Ala., Dec. 20.

Somewhat Old Beginners.

I am 61 years old and my wife is 64, but we are beginners with bees. I have now three bee-papers to read. I need not keep bees for a living, but all my children have places of their own, so I must have bees and poultry in order to have something to work at. From 5 colonies I had bought last spring, I put into the cellar 21 this fall, but had only about 100 pounds of honey.

JAMES OLESON.

Chippewa Co., Minn., Dec. 18.

Bees Did Fairly Well.

My bees did fairly well the past season, considering the general complaint of a poor season. I had only eight colonies, and they averaged 40 pounds to the colony. I had no swarms during the harvest.

This is the first year that I ever took any interest in the bee-subject, but I am very much interested in it now.

A. B. CROSS.

Meigs Co., Ohio, Dec. 19.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, Jan. 9.—The trade is not active in comb honey, many of the retail dealers being supplied with sufficient stock to meet demands for some time to come. Prices are quite steady with 13c for best white, off in color, etc., including amber grades, 100/12c; dark, 9c. Extracted 60/7c for white; amber and dark, 50/6c. Beeswax, 27.
R. A. BURNETT & CO.

DETROIT, Jan. 2.—No change in supply of honey as to quality, but prices are somewhat lower than last quotations, viz: Fancy white, 15c; No. 1, 12 1/2c; Fancy dark and amber, 9 1/2c. Extracted, white, 60/7c; dark, 50/5 1/2c. Beeswax, 25 1/2c.
M. H. HUNT.

INDIANAPOLIS, Jan. 4.—Fancy white comb, 12 1/2c; No. 1, 10 1/2c. Demand fairly good. Dark comb honey is being offered at 8 1/2c with almost no demand. Clover and basswood extracted, 6 1/2c. Beeswax, 20 1/2c.
WALTER S. POWDER.

NEW YORK, Jan. 2.—The market is well supplied, especially with dark. Demand is fair for white and dark, and off grades are being neglected. We quote:

Fancy white, 12 1/2c; No. 1 white, 10 1/2c; amber, 9 1/2c; dark, 7 1/2c. Stocks of extracted of all kinds are light. White, 6 1/2c; amber, 6c; dark, 5 1/2c. Southern, in barrels, 60 to 65c per gallon. Beeswax dull at 20 1/2c.
HILDEBRETH BROS. & SEGELKEN.

BOSTON, Jan. 9.—Fancy white, 13 1/4c; A No. 1, 12c; No. 1, 11c; light amber, 9 1/2c; buckwheat, no call. Extracted, white Northern stock, 7 1/2c; Southern stock, 6 1/2c. Beeswax, 27c.

The demand for honey seems to have dropped out of sight during the holiday season, but now that it is over we hope to see a better call for it. There is abundance of stock on hand and it now looks as if the expected shortage would not materialize.
BLAKE, SCOTT & LEE.

BUFFALO, Jan. 6.—Our honey market is very quiet. Finest 1-pound white fancy combs move slow at 12c; often 11c; excellent grades, 9 1/2c, and dark, poor, etc., 6 1/2c. Extracted, 5 1/2c. Beeswax, fancy pure, 28 1/2c; dark, etc., 24 1/2c.
BATTERSON & CO.

CLEVELAND, Jan. 2.—Fancy white, 13 1/4c; No. 1 white, 12 1/4c; A No. 1 amber, 10 1/2c; No. 2 amber, 9 1/2c; buckwheat, 8c. Extracted, white, 7c; amber, 6c; buckwheat, 5c.
A. B. WILLIAMS & CO.

MILWAUKEE, Jan. 9.—Fancy 1-lb. sections, 12 1/2c; A No. 1, 12 1/2c; No. 1, 11 1/2c; dark or amber, 8 1/2c. Extracted, in barrels, kegs and pails, 6 1/2c; dark, 5 1/2c. Beeswax, 25 1/2c.

The condition of the market is favorable for shipments of honey, especially of best grades, which are in small supply. The sales are moderate, but we are expecting an increased demand and good trade this spring.

A. V. BISHOP & CO.

Convention Notices.

Wisconsin.—The Wisconsin State Bee Keepers' Association will hold their annual convention at Madison, Feb. 9 and 10. It promises to be the best held for years. Every bee-keeper is urged to be present. An interesting program is being arranged.
Platteville, Wis. N. E. FRANCE, Sec.

Minnesota.—The following program has been arranged by Pres. E. B. Huffman for the meeting of the Southern Minnesota Bee-Keepers' Association, which meets in Winona, Minn., Jan. 25 and 26:

Opening address—Pres. E. B. Huffman.
"How to prepare bees for winter, and the proper way to care for them"—Frank Yahnke.

"How to prepare a colony of bees for the introduction of a queen, and the best way to introduce her"—C. A. Gile.

"Which is the most profitable to work for, comb or extracted honey, and the most suitable size hive for the same?"—E. B. Cornwell.

"What is the best size of hive, frames and sections for general use?"—S. W. Judge.

"The best way to manage bees for increase"—W. F. Martin.

"What is the best way, and the kind of hive to use, in stimulating bees, and also feeding them?"—John Turnbull.
Winona, Minn. C. A. GILE, Sec.

Order Early

There are indications that the demand for SUPPLIES will be very large this season, and everyone should order as early as possible. We have large facilities for manufacturing all kinds of

Bee-Keepers' Supplies,

And will serve our customers as quickly as possible.

Eastern Bee-Keepers!

Seven years ago we started an Apiarian Supply business in NEW YORK CITY, as we saw an opening here. That we made no mistake in this is shown by the large demand for Supplies and our constantly increasing trade. Our aim was to furnish Supplies promptly. In many cases bee-keepers find the freight on Supplies from the Western factories is as much as the cost of the goods. In buying near home you not only save freight, but get your goods much more promptly. We keep several carloads of

Hives, Sections, Foundation, Etc.,

always in stock ready to ship, and the prices will be found RIGHT. We also run two apiaries for honey and sell BEES AND QUEENS. If you expect to use anything in the Apiarian line the coming year, you will do well to send for our catalogue. We would be pleased to quote you SPECIAL PRICES on what you want, as this is our dull season, and we can afford to sell for small profits. Hives, Sections, etc., are made in Wisconsin, where lumber is low, and the best can be had.

Our Special Price on Foundation, Hives and Sections will make you Smile.

Write for it, stating the quantity you can use. DEALERS should write for our '99 discount sheet which is now ready to mail.

CONTRIBUTED ARTICLES

Imported Queens Better than Home-Bred, Etc.

BY G. M. DOOLITTLE.

HAVING been laid aside for some time with fractured ribs and la grippe, a lot of correspondence, by way of questions, has accumulated, and with the Editor's permission I will answer some of them through the columns of the American Bee Journal.

The first one I come to reads: "What do you think of the claim made by some that imported queens are superior to those bred in this country?"

From years of experience with both imported Italians

and the pains in breeding that the Americans do; for, if I am correctly informed, the most of the queens sent over here, unless it is very lately, are from a promiscuous selection, mostly taken from second and third swarms, on account of these swarms not being likely to build up to make good honey-gathering colonies for the next season.

How much different the mode practiced by our best breeders! Queens are selected for generations, each selection being made from those which are the most hardy, and give the best results in every way; then the very best specimen is selected from the next generation, and so on, always selecting the queen each time which scores the highest number of points, till perfection is well nigh reached. It seems strange that any one can believe that queens from a promiscuous importation will equal queens bred with such care and painstaking.

Where people are not satisfied with the stock they have, my advice would be for all those so situated, to buy an imported queen if they think them superior, and a home-bred one from some reliable breeder, and try the two equally, rearing as many queens from one as from the other, when they soon can tell which is the best for them. If they do

Group of Queen-Cells.

Bees at Work Building Comb.

not choose the home-bred queens, I do not think that any proof can be found to substantiate such a claim. In fact, I believe the balance of proof is on the other side. Very many have written me that they would not exchange their home-bred queens for imported stock on any account, and their yields of honey are much increased above what they were when they first obtained Italian queens from the old country. Queen-breeders on the other side of the water do not take

not choose the home-bred queens, then they will be different from the majority of cases coming under my notice.

GERMAN BEES—HOW LONG DO THEY LIVE?

Another correspondent wishes me to tell how long the German (or black) bee will live. Well, about as long as the bees of any other variety, tho I used to think that the Cyprian bees were a little longer lived than any of the other

varieties I ever tried. But as they were so vicious that no one could tolerate them, the length of life was not of sufficient importance to cause them to become a favorite with the apiculturists of the United States.

The length of life of any bee depends upon the season of the year when the trial is made, and the condition of the colony. If in the summer or working season, 45 days will be about the length of life the worker-bee will enjoy; while if during the fall and winter months, the time will be found to be from six to eight months.

For instance, if we take away a black or German queen about the middle of June, and introduce an Italian queen in her place, we shall have Italian bees hatching 21 days thereafter, which date we are to mark on the hive, as the time we are to count from, as there will be no black bees emerging from the cells after this. At the end of 40 days the black bees will be found to be very few in numbers, while at the end of 45 days not a black bee will be found in the hive.

If the colony is made queenless at the end of 20 days after the Italian queen was introduced, then the length of life to the workers will be prolonged on account of their not laboring so hard, for queenless bees never have the energy shown by those which have their mother with them; and it is the amount of labor done which has to do with the length of life given to our pets.

Again, if the change of queens is made during the fall months we shall find plenty of black bees the latter part of spring, altho they soon disappear after the active labor of honey-gathering comes on.

This length of life has much to do with spring dwindling, with preparations for winter, making new colonies, our surplus crop of honey, etc., and therefore should be understood by all. It is impossible to secure a good crop of honey where the most of the bees are nearly worn out with age just as the harvest is commencing; and where bees become uneasy in winter, and wear themselves out with worry, spring dwindling is sure to occur. So, all old bees in the fall will result in empty hives the next spring; and a divided colony, so made that one part contains all old bees results in no profit from that part. It is well to be practical along these lines, as well as all others pertaining to bee-culture.

ROBBING DURING THE HONEY SEASON.

Another bee-keeper wishes me to tell him through the columns of the American Bee Journal, whether bees are subject to robbing during a flow of honey, when the same stops for a day or two, writing thus:

"I see it recommended in a certain book that we should not try to remove the surplus honey from the hive immediately after a shower, in the honey season, for fear of robbing, thereby causing the bees to become very cross; the reason therefore being given that the shower had washed the honey from the flowers, hence the bees are eager to rob. Do you find this so? With me the bees do not offer to rob till a day or two has elapsed after the bees have been gathering honey plentifully."

I would say that all my experience goes to prove that bees are not liable to rob during a honey-flow, for at times of plenty of honey they are the least liable to rob of any time of the year when they can fly. If the honey-flow has been only a very meager one, then bees may be inclined to rob after the stopping of that meager flow, but if the yield has been abundant then the case is different. During a heavy yield of honey which has lasted a week or more, the bees seem almost glad of a rest for at least 24 hours, especially if the weather is dull. I have taken off honey hundreds of times immediately after a shower where there had been an abundant yield before, without being bothered in the least by bees trying to rob. At such times each bee is so full of nectar that, if squeezed a little, it will throw the honey out on its proboscis; and if jammed a little too hard the honey-sac, filled with honey, would burst through the sides of the abdomen.

When bees secure honey rapidly, each bee takes all it can into its honey-sac, then throws it out again, and so on to evaporate the watery part of it; for all nectar when gathered is so thin that it needs much reducing before it is of the right consistency to be stored in the cells and sealed over. After all the thin nectar has been evaporated, then the bees begin to look around for more, and if the flowers fail to secrete any, robbing is the result, where honey is left exposed; and all wise persons will avoid leaving honey exposed at such times, or, in fact, at any other time.

Onondaga Co., N. Y.

The Best Size of Hive Considered.

BY C. DAVENPORT.

FROM what has since been said by some, I believe that my position in the discussion that took place sometime ago in regard to the best size of hive was somewhat misunderstood; on this account, perhaps, I may be allowed to say a few more words on the subject in this discussion.

I advocated the 10-frame hive as the best for the majority, or, in other words, for those who did not have the time or inclination to feed, which is more often necessary with 8 frames than 10; but I prefer, and use, a hive containing only 8 standard-size frames, and with them I can obtain more honey per frame, work, feed, and capital invested considered, than I can by using larger hives. But I have no doubt 10-frame hives, taking a series of years, would give better results to the average bee-keeper, for, as a rule, it requires a much closer attention to details when using 8-frame hives, but many years' experience with hundreds of colonies, and with hives of various sizes, has convinced me that a 10-frame hive is better than a larger one for the production of comb honey in the Northern States, and I will briefly explain why.

In the first place, here we have at the first but a short season. From the time the weather is favorable for brood-rearing there is what might be called but a short time until the white honey harvest commences, and I have found but very few queens that would keep more than 10 frames filled early enough so that the eggs would develop into field-bees in time to gather this white flow, for the fact should be borne in mind that it takes about 35 days for an egg to develop into a field-bee. Later, tho, a large percent of queens might require more than 10 frames if they were given the opportunity to develop there full laying capacity, but in this locality it is not only not profitable, but is a loss to have an immense force of bees reared at this time, for before they come into action as field-bees the white honey harvest is over; and while we sometimes get a fall crop here, many of these bees will be too old to be of much service in gathering a fall flow. But if otherwise, the dark honey they would be able to gather in the fall would not be worth the white honey which it has taken to produce, and which they have consumed. But, again, even if it was, it would be no plea for allowing them to be reared, for in the natural course of events, even with 8-frame hives, there will be a force of field-bees large enough to secure anything in the nature of a fall crop, which is likely to occur in this locality.

Some who have argued in favor of large hives have practically admitted all I have just said to be true, with the exception that it is still profitable to rear a large force of bees toward the latter part of the season, for in that case it is claimed colonies will go into winter quarters stronger, and have a much larger force of bees when brood-rearing is commenced in the spring; and that because this extra force of bees is present they will breed up and develop much more rapidly.

But the fact of this matter is, that in this locality at least, it is by no means the rule that these extra-large colonies will be any stronger by the first of next May or June than are medium-sized colonies of the previous fall. But I can understand that in some localities, where the conditions of the season are different from what they are here, they might be. Let me explain why they are not, as a rule, here.

In the first place, my present belief is that the most practical way to winter bees in this State is in some repository under ground. This means confinement of from four to five months, and bees reared the previous season and confined for this length of time live but a short time after they are put out in the spring—but a few days, comparatively speaking, of active work and they are gone. Of course, they last longer some seasons than they do in others, according as the seasons vary.

Here, in the spring, owing to reasons that I do not fully understand, extra-strong colonies in large hives seem to lose a larger percent of old bees sooner than do medium-strong colonies. One of the principal reasons for this is, I believe, owing to the fact that in the spring we have many cold, sunshiny days, when it requires all the force of a medium-sized colony to keep their brood warm. Extra-strong colonies having a larger force than is required for this purpose, more of them fly out and wear themselves out sooner in the chill air, roaming barren fields; and when a strong colony in a large hive becomes reduced to normal size in the spring, it is at a disadvantage so far as the size of hive is concerned.

Now, I do not wish it to be inferred that I am in favor

of weak colonies, for in this locality one of the main factors of success in the science of production of honey is to have strong colonies at the proper time; but in the production of comb honey, at least, it is also a very important factor to have these strong colonies in the right size of hive.

Let us take two strong colonies of equal strength at the beginning of the white honey-flow—one in an 8-frame hive, the combs of which are filled with brood and stores. If the other is in say a 12-frame hive, there will be, as a rule, two or three empty combs; this means so much less white section honey, for no colony will do section work with unoccupied comb in the brood-nest.

But it is claimed by many that a colony in a small hive is much more liable to swarm. This is not, however, usually the case here, for of the two colonies I have just described one is about as likely to swarm as the other, but the one on 8 frames will swarm a few days sooner, the other following suit as soon as, or very shortly after, the empty comb in the brood-nest is filled. That is, in a good season with nothing done to prevent or discourage swarming, for 12 frames of comb will not prevent swarming, 16 sometimes will, 24 will as a rule prevent all desire to swarm with any colony, provided they are also given additional room if it is required. But here it is a better season than we have had for sometime when a colony on even 16 frames will do much section work, that is, with only the bees which are the product of one queen. But I believe it is a fact which has often been announced, that a colony, no matter how strong, will very seldom swarm in any season if it has all the drawn empty comb in large frames that it can occupy. But can this means of preventing swarming be profitably practiced in even the production of extracted honey? I believe not, in my locality, unless the working force of two or more colonies are thrown into one.

Some experiments I have made in this line I may describe later.
Southern Minnesota.

Why a Poor Season—Queen with the Swarm.

BY C. E. MEAD.

I WISH to tell why the past season was the poorest I ever had for honey. In March my bees flew strong, and with so many bright, well-favored young bees, I thought that they would need surplus room in fruit and dandelion bloom. But northeast winds prevailed cold and damp from off Lake Michigan. The field-bees that ventured out were chilled, and never got back to the hive. When I reach home at night I would look first at the hives, and see the ground in the yard covered with bees loaded with pollen, honey and water, chilled and dead on the ground. Of course, what I saw was a small proportion of the loss, as most were chilled away from the yard.

I contracted the hive-entrances, and made them as warm as I could. Still the wind held in the northeast. It would be warm in the middle of the day and then clouds or a sudden, stiff lake wind would cut off all that were out. This kept up till the middle of June, with the result that my bees were weaker in numbers June 1 than on March 1, tho all the bees were young ones. They seemed to jump from weak colonies to full-sized ones by July 1.

In the first part of August the northeast winds again came on, and kept in that quarter the balance of the season, so my report is only 20 pounds of extracted honey per colony.

The most ambitious colonies suffered the most. Beekeepers further away from the Lake, as the winds got warmed up by the time they got there, did not have the losses that I did.

Heretofore my hives have been full of bees when the first honey came—sometimes 20 Langstroth, and 16 Langstroth frames in two bodies high, and run that way through the season.

A YOUNG QUEEN WITH THE SWARM.

I have always said that the old queen always went with the first swarm. Well, she doesn't. I sold a queen to a man some eight miles away, and its colony swarmed in May. As he requested me to look over the new swarm to see if they had honey enough to last through the cold, wet, northeast rain, I found a big young queen with unclipt wings. I lookt over the parent colony, and found the old queen with elipt wing, and all the young queens and queen-cells destroyed, and combs full of brood and eggs; and the hive two stories high very strong in bees. I account for it in this way:

The bees wanted to swarm; the bad weather kept them

back until the young queen got out, and as she could fly she went with the swarm, and the old queen crowded back into the hive. In the face of the bad weather they did not wish to swarm again. If it had been a case of superseding, the bees would not have destroyed all the cells, but would have reared one to share the hive with the old queen till the honey-flow became slack again; and then I think they stop feeding the old queen and let her die.

I found an old queen nearly dead on the bottom-board and fed her, and divided the colony (taking away part of the bees and the young queen), and then fed the old colony, and reared three fine young queens. I let one stay in the old hive and superseded the old queen.

I have tried three times to save a valuable breeder when she seemed to be as prolific as any queen, and for some unaccountable reason the bees were determined to supersede them. By rearing the cells in other colonies, cutting them out when "ripe," in each of the three cases the old queen died before spring. No matter what you may think, *the bees know before you can detect it*, when a queen is beginning to fail. Let them have their own way about that.
Cook Co., Ill.

Winter Work in and for the Apiary.

BY F. A. SNELL.

WHERE the bees were properly housed in November, as they should be in our cold winter climate, not a great deal of work remains to be done with the bees, but it is important that this be done when necessary. If the bees are wintered out-of-doors, when snow-storms occur and the snow drifts so as to obstruct the hive-entrance and exclude air, it should be shoveled away as soon as the storm is over. If allowed to remain it may soon thaw and seal the hive-entrance with ice, and smother the bees.

With those who give no winter protection this work is of inereast importance. I do not believe in having our bees buried in snow. The snow covering makes the hives warmer while it remains over them, and is almost sure to start the bees to brood-rearing, especially as late as the last of January or February, which is undesirable in our latitude during winter. There is danger of our bees having diarrhea from the activity and inereast consumption of food thus caused, unless they have frequent flights, which is not apt to be the case.

Our bees, if buried for a time in snow, and a thaw coming later and melting the snow off, leaves the hives much colder if followed by cold weather, and the brood reared before is very liable to be chilled, the older bees die off, and by spring we have the so-called spring dwindling, which was caused by the early activity in brood-rearing, and the connecting increase of food consumed.

The dead bees that accumulated on the bottom-boards should be removed about once each month, wherever our bees are wintered, and the hives be kept sweet and clean by doing so.

When the bees are wintered in the cellar, the hives and cellar floor should be kept cleared of dead bees, and if signs of mice are found, traps should be set, and the mice caught. It is only a few hours' work each month that is needed to keep the hives and surroundings clear.

Hives, if to be made, can be put up at this time of the year, honey sections and cases put together, and be out of the way when the busy spring-time arrives.

As work is not crowding at this time of year, and our evenings are long, considerable time should be given to the laying of plans, and reading up in our pursuit. It is an excellent plan to get out the old bee-papers and look them over, always to find valuable ideas that we had nearly or quite forgotten. We will find numerous articles that will give us light on points we most need; read, too, each new number as it arrives in the mails. If not a subscriber to a good bee-paper, become one right away, for success depends very much upon the knowledge we possess. This we can only get by study and experience. At least one good book on bee-culture should be obtained and studied, which will prove a very pleasant work indeed. I well remember, over 30 years ago, when I was a boy, how anxiously I lookt for the then monthly arrival of the good old American Bee Journal, to which I at that time became a subscriber, and which I have taken and read ever since. The work, if such it can be called, was then, and has ever since been, a very pleasant one. I eagerly read all the books on bees that I could find. I was a real enthusiast. I believe no one can

reach even a moderate degree of success with bees unless he becomes enthusiastic.

Read, learn, study, and practice, are needed requisites to become a good and successful bee-keeper. For myself, I can find no more pleasing and interesting reading-matter than that upon bee-keeping, and such has been the case from the time I was taken with the bee-fever.

I have known of no one who was not enthusiastic in his calling to meet with much success. The present winter should be improved by thoroughly studying and learning our pursuit, at least by those new in the business.

Carroll Co., Ill.

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[Questions may be mailed to the Bee Journal, or to Dr. Miller direct.]

Arranging the Hives Comb or Extracted Honey.

1. In locating a small apiary of from 30 to 50 hives, which method of arranging the hives would you consider preferable—(a) leave a space of about three feet between each two hives (the hives will be in a long row); (b) or, group the hives in threes, leaving about a foot space between the center one and those right and left of it, and allowing about six feet between groups; (c) have you any better plan to offer than either of the above?

2. I can set the hives to face east (straight) or south-east (at an angle) which would be the better?

3. In your locality, and taking an average season, what would you consider a fair cash return from 10 colonies—(a) worked for comb honey, (b) for extracted? IOWA.

ANSWERS. 1. The groups of three will make it easier for bees and young queens to find their hives, but it will not be very convenient for the operator to get at the middle hive in a group of three. Better than either of these plans you will probably like having the hives in pairs, with not more than about four inches between the two hives in each pair.

2. You will not be likely to find any material difference.

3. I don't know. Perhaps \$25 for either.

Temperature of a Moist Cellar.

Does it make any difference whether the temperature in the bee-cellar is high or low in regard to moisture in the hives in winter? IOWA.

ANSWER. Yes, more moisture will collect in the hives in a cold than in a warm cellar, other things being equal. If a cellar is very damp, it will need to be kept warmer than if dry.

Quintet of Questions.

Last year I started in the spring with 12 colonies, increased to 19, and received about 200 pounds of honey. In this section the past year was very poor indeed.

1. Do you approve of full foundation sheets for a new swarm in an 8-frame dovetailed hive? The reason I ask about foundation is, if you use full sheets, will not the deposit of wax the bees go with go to waste?

2. Which do you consider the more valuable for hives, basswood or pine?

3. Where can I get them, and what will a colony of Cyprian bees cost?

4. I know of some basswood trees about three or four inches through that I can get. Will it pay me to get them and reset near my apiary? How long will it be before such trees will bloom? There is quite a large locust grove not far from my apiary from which my bees get much honey.

5. Is rye flour the best for feeding bees for pollen when they cannot take a flight? NEW YORK.

ANSWERS. 1. Yes, it makes sure of having your combs all worked. It also makes sure of straighter combs than you can get in any other way. The bees will draw out the foundation only a little way, and then they will find use for

the wax they have in finishing out the cells. Some excellent authorities prefer to have the first half of the combs built with starters, having full sheets of foundation for the last half. But it takes a good deal more care to get straight worker-combs without foundation.

2. Pine, by all means. Basswood is one of the worst woods to shrink and swell, and is not fit for hives or frames.

3. I don't know.

4. Very likely it may pay well to do so. It depends somewhat on circumstances. If they are within a mile, and not too crowded, so that if left they would grow up into good trees of their own accord, then it might not pay to touch them. But if they are crowded, or likely to be destroyed, it will be well to get them, especially if not plenty about you. Sometimes others will take and plant them as shade trees in reach of your bees. I've seen them blossom when five or six inches through.

5. Better not think of feeding rye or any other substitute for pollen when bees cannot fly. Leave them in quiet. Substitutes for pollen are to be fed in the open air when it is pleasant for the bees to fly, but have no natural pollen to work on. Just as soon as they can get genuine pollen they will desert the imitation article. What is best to feed is partly a matter of convenience. I think ground corn and oats has been more satisfactory than anything I ever tried, and I've fed bushels of it. The bees will work out the finer parts, and the coarser part that's left can be fed to stock.

Hive-Stands Hiving Swarms Foundation in Sections—Spring Feeding Finding Black Queens.

1. How is the best way to make hive-stands? I have mine of four posts driven into the ground about six inches high. Is there any better way? I wish to put my hives in groups next spring, the same as you have yours. How much space should there be between each group? Please give full particulars.

2. If I have a swarm in the forenoon, putting surplus case of the parent hive on the swarm immediately, can I wait until 5:20 p.m. before removing the parent hive to the new location, and putting the swarm on the stand of the parent hive?

3. When hiving swarms and putting section-cases of the parent hives on the swarms with excluding-board, how do the drones get out?

4. Please give the best way to put foundation in sections. I have been using full sheets (3 $\frac{3}{4}$ x 3 $\frac{3}{4}$) but had two cases on a colony of Italians that were not built down to the bottom.

5. Do snakes ever trouble bees? A neighbor of mine told me he saw a snake near the entrance of two of his hives, and a few weeks later noticed they were weaker.

6. Give some good way to feed in spring. My book does not give full particulars. I would like to feed over the brood-nest. What kind of feeder do I want, and how do you keep the hive warm without enameled cloth? My hives have board covers.

7. I have a few colonies of black bees to which I would like to give Italian queens, but I am unable to find the old queens. Can you give me a sure way of catching them? NEW YORK.

ANSWERS. 1. The best way to have hives arranged depends somewhat on the lay of the land, and other circumstances, but as a general rule it is doubtful whether any way is better than to have them in groups of fours, two hives side by side, and two others back to back to the first pair. Make a stand, not for each hive, but for each pair. It will take less work than to make a separate stand for each hive, and it's much easier leveling the larger stand. Set two hives side by side, facing the same way, with four or five inches space between them. Your stand must be just of the right size for those two hives to sit comfortably upon it when placed in that position. Each stand requires two pieces of board six inches wide. Common fence-boards are all right. Cut two of the pieces four or five inches longer than twice the width of a hive. Cut the other two pieces about as long as the bottom-board of your hive. Now nail the two long boards on the two short ones and your stand is finished. Exceedingly simple, isn't it? Lay your stand on the ground where you want to place your hives, use a spirit-level, and make it perfectly level the long way. That will make the hives level from side to side. As to the other direction, let the stand slant a little forward, so water will run out of the entrances of the hive. Of course, if the ground is not perfectly level, you will have to block up the

stand to make it level, and in any case the stand should be blockt up so it does not rest upon the ground at any part. This is merely as a matter of economy to keep the stand from rotting. The long boards of the stand will be uppermost. If your rows run north and south, one pair of hives in the group of four will face east, and the other pair will face west, the two pairs standing back to back, with perhaps four inches between them.

2. If I understand you correctly, it wouldn't be advisable. Your idea seems to be to hive the swarm wherever it happens to cluster, put supers on, and let it stand there till evening. During that time some of the bees will have markt their location and commenced work in the fields, and when you move them there will be some trouble next day about their finding their home. But if circumstances are such that you must leave them till evening, don't change the super to the swarm till you move it to the new place.

3. They don't get out. They stay, and in course of time die there if not let out. But it doesn't seem to trouble the bees a great deal to have their dead brothers lying around.

4. If you want to make sure of having sections built down to the bottom, put in a bottom-starter $\frac{1}{2}$ or $\frac{3}{8}$ -inch deep, and let the top starter come down within $\frac{1}{4}$ or $\frac{1}{8}$ -inch of the lower one. $\frac{1}{8}$ is probably better than $\frac{1}{4}$. I have used these bottom-starters for years, and with great satisfaction.

5. I have found snakes under hives a good many times, and sometimes in them, but I never thought they did any harm.

6. Probably nothing would suit the bees as well as to be fed with combs of sealed honey. But as you say you want to feed over the brood-nest, it is likely you haven't the combs of honey. To suit your desire, it isn't likely anything would do better than the Miller feeder. As furnisht by supply dealers, it is usually made to fit 8-frame hives, but it could be made of any size. All you would have to do would be to put the feeder on the hive, put in some sugar, pour on some water, either cold or hot, then put on your board cover. If you don't want to be to the expense of a feeder, and are willing to take a little more trouble, use the crock-and-plate plan so many times described in past numbers. If you can't find it easily, ask for it about a month before you want to use it and it will be described again.

7. Hunt carefully. Don't get the bees stirred up to run, and if they start to run give it up till another time. You can strain out the queen with a queen-excluder. Put the excluder, or queen-trap, at the entrance of a hive containing one or more frames of brood. Shake or brush the bees down in front of the entrance. The workers will go in, but the queen will be outside with whatever drones are there. Another way is to put an empty hive over another, having an excluder between. Have one or more frames of brood in the lower story. Brush the bees into the upper story. The workers will go down to the brood. If they don't go fast enough to suit you, poke them up a little. The queen will be left above.

Question About Getting Apis Dorsata.

How can I have the giant bees sent from India? How should they be sent by mail or express? Would they have to be fed on the way? Will they live in this climate? I belong in Bombay, and can get the bees sent to me if I give directions about sending them. CONNECTICUT.

ANSWER.—It is so difficult to get them to this country that no one has yet succeeded in getting them here. Perhaps the only way you could succeed would be to have them sent with some one coming this way who would see to properly supplying their wants on the way.

Keeping Young Queens.

If one rears queen-cells like Doolittle does, would it do to put one cell in a cage and three or four cages and cells in a nucleus, let them hatch and confine them in cage until the first queen has mated, and release one at a time as fast as the mated queen is removed? Would bees feed caged queens if the plan would work? A great many cells could be saved in a season. NEW YORK.

ANSWER. You can keep a number of cells in cages in a hive, and the bees will take care of the young queens generally as they emerge, but you must have each young queen in a separate place to be fertilized and commence laying. You may, however, have two queens or more taken care of

by one colony, if the queens are barred from each other and far enough apart. If a laying queen is in the lower story, you may have a young queen in the third or fourth story, with an entrance there, and she may go out and become fertilized, and then begin laying all right in that upper story.

Feeding Bees in Winter.

I have one colony to feed. Tell me how to feed them at this time of the year, and what is best to feed.

KENTUCKY.

ANSWER. It's a bad thing to need to feed this time of the year. Be sure to look out for that next August or September, and see that every colony has more than enough to keep it through the winter. The best thing to be done now is to give the needy colony a frame of sealed honey, putting it close to the cluster of bees. Like enough you have no such frame of honey, and must resort to candy. Use best granulated sugar with enough water to dissolve it (it will take nearly half as much water by measure as sugar), boil till threads of it break like pipe-stems when dropt in cold water, pour in a greast dish so as to make cakes half an inch to an inch thick, lay these on top of the frames and cover up warm. Be sure not to burn the candy.

CONVENTION PROCEEDINGS

Proceedings of the Colorado State Bee-Keepers' Convention.

(CONTRIBUTED BY THE SECRETARY.)

[Continued from page 38.]

SINGLE-TIER VS. DOUBLE-TIER SHIPPING-CASES.

J. N. Pease—Is a one-story shipping-case better than a two-story?

F. Rauchfuss—I have had no experience in shipping the one-story cases. When we ship by the carload, we want them all of one kind.

Mr. Pease—Don't the Chicago people want the single-tier cases?

F. Rauchfuss—Altho the Chicago market may prefer the single-tier, we have so far found no objection to our double-tier case. It is not so much a question of convenience to the buyer as of convenience to some other people. In the East, thin honey may do more damage in double-tier cases than in single-tier. But here, that is not very much of an objection. The honey is heavier. If a double-tier case is used, always put a sheet of paper between the two tiers; then if there is a little leakage it will not injure the lower tier.

Mr. Adams—Orders to us in northern Colorado have required double-tier cases this year. No reason was given.

Mr. Pease—It is easier to examine the honey in single-tier cases.

Mr. Honnett—A firm in Chicago said they preferred 12-pound cases, which of course are single-tier.

WISCONSIN VS. OHIO BEE-SUPPLIES.

QUESTION—Would it not be to our interest to insist that our supply dealers keep more Wisconsin than Ohio goods?

This question was mainly discust with reference to sections and shipping-cases, tho hives were also toucht upon. The preference of those who exprest themselves was for Wisconsin goods. It was also said that it was simply a business question, as there was no difference in prices; but there seemed to be more demand for Ohio goods, because the Wisconsin factories dealt in wood alone, while other articles as well could be ordered from Ohio.

FLAT COVERS AND SUPERS IN WINTER.

Mrs. Booth—If we want anything good, we want good hives. I don't like the flat cover for wintering. I will have to put supers on mine in order to get air above.

Prof. Gillette—I use supers in winter, filled with leaves.

Chaff may be used. I have had no experience with any other than flat covers.

E. Milleson— Anything may be used in the super which will not attract mice.

M. A. Gill I have become thoroughly converted to the flat cover. A colony of bees in Colorado should always have the super on. I use leaves. In this climate, $\frac{3}{8}$ -inch stuff with light nails will not stay in its position in the cover. The Higginsville cover is not reversible; it is light, and after the first year it shrinks. A cover of $\frac{3}{8}$ -inch stuff, thoroughly painted on both sides, is best. I have noticed covers while inspecting three or four thousand colonies, and have found the flat cover best.

W. W. Whipple I have used the flat cover. I fix up my bees the last of August. I use no blanket, but let them seal the cover tight. I tip up the hive two inches, with plenty of ventilation below, and leave until spring. I have no trouble in wintering bees.

MORE ON THE SUBJECT OF SPRAYING.

Prof. C. P. Gillette, Professor of Entomology at the State Agricultural College at Ft. Collins, then read a paper. Before doing so, he again referred to the spraying law, saying it was never necessary to spray until the blossoms had all fallen, and that to get the best results it is better to wait until a week after. There will be some trees, such as the Duchess, which will bloom early, and if one waits until a week after the late trees have bloomed, the early trees will have closed the calyx, so that the poison cannot enter in. Hence it is best to keep watch of the early bloom, and not spray the whole orchard at once. If ever necessary to spray for fungoid diseases, the Bordeaux mixture should be used. This is harmless to bees, and the only effective remedy for those diseases. The following is Prof. Gillette's paper:

Experiments with Drawn Foundation.

Last spring I obtained a quantity of drawn comb foundation from the A. I. Root Co., for the purpose of comparing its use in sections with the use of the ordinary thin foundation. In order to make a proper comparison the sections were filled half with drawn and half with plain foundation, the foundation extending about two-thirds of the way down in the section so that the lower third would be, in each case, all natural comb.

There was no question but what the bees went to work more freely upon the drawn foundation. Some of the colonies worked for several days upon the drawn foundation before beginning on the undrawn.

They do not, however, begin storing honey at once in the partly-drawn artificial cells. They never fail to go over every part of the surface of the cell with their mandibles, so biting and roughening it as to render it more translucent. After the cells had been worked over, and before they had been drawn out farther, the thickness was found to be reduced about one-sixteenth of an inch, or, in round numbers, the whole thickness was reduced one-sixth.

Another advantage from the use of the drawn foundation was in the tendency to unite the sides quickly and completely to the section without leaving holes for passage-ways. Where there is a thin foundation only, this is often done, but the bees seem to be loath to tear down the comb-cells for this purpose. It was also noticed that sections having the drawn foundation were, on an average, built more strongly to the sections, and with fewer passage-ways through the sides and corners.

The sections on being removed from the hive were as white and beautiful as any, and I doubt if any but the most notional would detect an unpleasant flavor or thickness to the comb. But if the honey be extracted and the comb washed and examined, it will be noticed that the lower half of the cells, and the septum, are of an amber, or beeswax color, quite in contrast to the exquisite whiteness of comb that has been entirely made by the bees.

I found that after carefully removing the cells from the septum in natural comb that it would require an average of 18.8 square feet of the septum to weigh a pound. From similar computations I found that the septum of comb built from drawn artificial foundation only required 13 square feet to the pound. At the same time I found that the septum of the artificial drawn foundation, after the removal of the cells, would require 21.8 square feet to weigh a pound, which shows that the artificial septum, before it is worked, is lighter than the natural. This seemed to me to indicate very strongly that the bees, instead of thinning this foundation, really thickened it by adding to it.

To further test this point, I took samples of foundation

of three different weights, one being a very heavy product of home manufacture obtained from Mr. Frank Rauchfuss; another was a medium-weight brood-foundation, and the third was a good quality of very thin foundation for use in sections. In each case I carefully weighed accurately measured pieces of foundation before the bees had touched it, and then similar pieces of the septum of comb built on each kind of foundation, and the following table shows the results:

WEIGHTS OF FOUNDATIONS AND COMB SEPTA:

| | Heavy Foundation | | Brood Foundation | | Thin Foundation | | Drawn Foundation | | Natural Septum. |
|----------------------|------------------|--------|------------------|---------------|-----------------|---------------|----------------------|-----------------|-----------------------------|
| | Fdn. | Sept. | Fdn. | Sept. | Fdn. | Sept. | Fdn. | Sept. | |
| Weight per sq. inch. | 10.4 gr 11.0 | 7.8 gr | 8.8 gr | 4.7 gr 4.1 | 4.1 gr | 3.7 gr 2.7 | 2.9 gr 2.40 | 4.10 gr 3.20 | 2.05 grains 2.50 3.20 |
| Average weights. | 10.7 | 7.8 | 8.8 | 4.7 | 4.1 | 3.2 | 2.25 | 3.72 | 2.58 |
| Sq. feet in a pound. | 4.5 | 6.2 | 5.5 | 10.3 | 11.9 | 15.2 | 21.8 | 13. | 18.8 |
| Weight reduced. | 25 percent. | | 46.6 percent. | | 22 percent. | | Increase 67 percent. | | |

The table shows very conclusively, as do the samples of foundation and comb septa that I here show, that in cases where heavy foundation, or even the thinnest of ordinary foundation, is used, the bees thin the foundation before storing honey upon it.

The added weight in cases of drawn foundation seems to be due largely to thickened deposits made upon the septum along some of the angles, and not to an even distribution of the added wax. These thickened deposits may be plainly seen by looking through the comb towards the light. These deposits are much more abundant in some pieces than in others, and just what their occasion may be I cannot say. Perhaps the angles at the bottom of the cells are not just as the bees would make them, or perhaps there are other imperfections in the cell that the bees cover over. These deposits are absent in natural comb, and I find very few of them in comb built from ordinary plain foundation.

According to the weighings that I have made, the amount added is equal to about two-thirds the weight of the septum in natural comb, so the saving of wax from the use of the drawn foundation would not be as much as would at first seem.

On the whole, I am pleased with the drawn foundation, and would heartily recommend its trial, at least, by the practical bee-keeper who wishes to obtain the largest possible crop of comb honey. C. P. GILLETTE.

The samples of foundation and septa which Prof. Gillette past around for inspection were arranged in pairs, clamped between pieces of section-wood fastened together with light nails, and illustrated his points very fully and satisfactorily. Besides these were several sections of comb built on drawn foundation, etc. One of these contained a starter of the heavy brood foundation referred to, which had been blackened at the lower edge, and then left with the bees a short time. This showed the cells scarcely begun, but streaks of black where the foundation touched the wood at the sides and above, and also down at the bottom of the section, where the V-grooves fold together, showing that the wax obtained by thinning foundation may be taken away and used elsewhere.

Commenting on the reason for the deposition of wax in drawn foundation, Pres. Aikin said that when bees begin to draw out ordinary foundation they make the bases of the cells of a rounding or concave form. He inferred from this that the cell-base is first made concave, and afterwards flattened. When drawn foundation is given, the side-walls are so high that the bees may not be able to manipulate the bases, but, instead, they round out the sharp angles at the juncture of the wall with the base. The less side or cell wall to begin with, the better they will thin the base. He was also of the opinion that home-made foundation is not pressed so hard as the factory-made, and therefore is more easily worked by the bees.

Mr. Porter Do you suppose that bees ever gather wax to make comb? I had always supposed that wax brought in from outside was used in the same manner as propolis.

Prof. Gillette—I don't know. I might mention here a circumstance of a different nature that seems worthy of re-

mark. In an experiment to find the amount of honey necessary to produce a pound of wax, four pounds of bees were kept in a building, in hives, for three weeks. Some of them then accidentally escaped, and instantly went back to their old location.

C. H. Gordon then spoke of his intention of starting a semi-monthly bee-paper for the West, and his confidence in its success.

H. Rauchfuss—It all depends on what the paper will be. Pres. Aikin—Mr. Gordon consulted me on the subject. I told him it would unquestionably be a great thing for Colorado, tho I would not vouch for the Association.

Mr. W. L. Porter then read the following paper, on

The Wax-Extractor.

In all branches of business, success and prosperity come from saving of small things. It is so in bee-keeping. The honey has its origin and is stored in the most tiny drops in the flowers; the wax is secreted and formed in minute scales on the bee's body; and both, in their aggregate, amount to an enormous sum. From this we may learn a valuable lesson—that no matter how small a thing is, if it has value it is worth preserving.

The solar extractor is an invention which separates the wax by the sun's rays. In this bright, sunny climate there are many days in the summer when it can be used to an excellent advantage; and every bee-keeper who has a few colonies of bees should be the owner of one. To get the best results from the machine, it should be placed in a sheltered place where it will have the reflection of a fence or building. The machine should be loaded in the morning, with the glass and pan tipped to the south, by placing in the pan a layer of broken comb cappings from extracting honey, or the scrapings of sections, etc. The sun will do the rest, and at night a beautiful yellow cake of beeswax will be secured.

It should be of the right capacity for the work. For a few colonies any number up to 50 a small machine will do; one like the Simplicity, with glass 10x22 inches, is ample. But as the colonies increase, greater capacity of glass is needed. I have made a very effectual one this summer from a hot-bed sash, 3x6 feet, with a strip of corrugated iron for a pan.

One of the difficult problems with me has been to keep the residue from sliding on the pan, and either going into the wax-pan or damming up the screen, and preventing the wax from going through. To prevent this, I have found it an excellent plan to place a sheet of wire cloth on the bottom of the pan, with a few small cleats under the wire to give drainage. The roughness of the screen prevents the residue from sliding, and lets the melted wax drain through at once. When the wax is all out, the wire can be raised out, and a quick shake will throw all the residue into a box where it can be kept for kindling the fire, for which it is excellent.

Bee-keepers should be careful to save everything that has wax in it, as the demand for wax is constantly on the increase.

W. L. PORTER.

Mr. Foster I had difficulty in getting the wax into shape, until I used the plan of the Rauchfuss brothers.

F. Rauchfuss—The only point about that is the way the wax is caked. All other extractors have but one pan. Ours has a series of pans connected by overflows. This keeps the honey and sediment practically in the first pan. The best time to open and fill the solar extractor is early in the morning, to keep out the flies. If opened at any other time, flies and bees will be trapped and will become imbedded in the wax. One of our 4x4 feet extractors last season remelted 900 to 1,000 pounds of wax.

H. Rauchfuss The pans that form the wax have to be exposed to the sun until evening.

F. Rauchfuss It has never been advised to place an obstruction in front of the screen; but if there is nothing but the wire screen at the end of the pan, a great deal of fine sediment will go through. To avoid this, place some slumgum in front of the screen.

Mr. Adams I discarded wire screens, and used a piece of glass in front of the screen.

Mr. Porter Have you ever tried a wire screen on the bottom of the tray that holds the comb? I have discarded wire screen at the end. I use a piece of common wire screen.

Pres. Aikin—I tried a piece of wire screen on one portion of a 6x6 extractor. But then I was melting a great many combs. I found that sediment so entirely clogged the screen that the wax flowed over. I have anticipated using

four or five meshes to the inch. Not much will go through if it is not stirred; but it ought to be stirred if old combs are melted. Still, the screen is a good thing. In building a wax-extractor, do not build too small. A large one does not cost much more. You can put a large load in and let it stay a long time. It will surprise you to see how much drains out after several days, or even a week.

Mr. Foster I use a hot-bed 3½x10 feet, and put all my dishes in. I use the same thing to raise cabbage-plants in spring.

Mr. Sylvester In stopping the debris, I have found it a success to use excelsior for a dam.

A Member—What do you make your pans of?

Pres. Aikin I use tin pans. You must not use rusty tin or iron, especially if there is water with the wax.

H. Rauchfuss What discolors the wax in melting with water? Wax produced by the solar extractor, when remelted with water, turns greenish.

Pres. Aikin I suspect that we darken wax by using water. It may be iron in the water. I do know that the blackest combs, when melted by dry heat, yield nice yellow wax. But if you melt the same old combs in water, you get dark wax. That is a point in favor of the solar extractor. Altho I have melted tons of wax, I have never succeeded with water as I have with the solar.

Mr. Gordon—Cannot darkened wax be restored in the solar extractor?

Pres. Aikin To a limited degree, as the result of bleaching.

Mr. Adams I have tried sheet-iron, galvanized iron, and tin. Wax is blackened by sheet-iron, and sticks to galvanized iron.

Mr. Foster Can we depend on the solar extractor, when properly worked, to get out all the wax that can be obtained?

Pres. Aikin If you build a big solar you can. You can't get enough wax out of the residue it leaves to pay for the trouble of working it. You can with pains get a little more wax, but it will be as black as my boot.

[Continued next week.]

York's Honey Almanac is a neat little 32-page pamphlet especially gotten up with a view to create a demand for honey among should-be consumers. Aside from the Almanac pages, the forepart of the pamphlet was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample for a stamp; 25 copies for 40 cents; 50 for 60 cents; 100 for \$1.00; 250 for \$2.25; 500 for \$4.00. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

The Omaha Convention Report ran through 14 numbers of the Bee Journal, beginning with the first number in October, 1898. Now we have on hand quite a number of complete sets of that report, which we will mail for just 10 cents each. That is, 14 copies of the American Bee Journal for only a dime. There are doubtless a good many of our new readers who will be glad to get that fine report.

Langstroth on the Honey-Bee, revised by the Dadants, is a standard, reliable and thoroughly complete work on bee-culture. It contains 520 pages, and is bound elegantly. Every reader of the American Bee Journal should have a copy of this book, as it answers hundreds of questions that arise about bees. We mail it for \$1.25, or club it with the Bee Journal for a year—both for only \$2.00.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last. Better order at once, if you want a copy of this song.

GEORGE W. YORK, Editor.

United States Bee-Keepers' Association.

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., E. Whitcomb; Vice-Pres., C. A. Hatch; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GEN'L MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

VOL. 39. JANUARY 26, 1899. NO. 4

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

All Re-Elected.—There were 229 ballots cast in the election just held for General Manager and two members of the Board of Directors in the United States Bee-Keepers' Association. All were re-elected—General Manager Secor receiving 216 votes; for Directors, E. R. Root, 182; and E. T. Abbott, 150.

It seems that only about one-half of the membership voted. We hope that all paid their annual dues, for if the attempt is to be made, as now contemplated, to enforce anti-adulteration laws, more money will be needed to carry on the work. This is a matter in which every bee-keeper in the land is interested, and all should help in the work.

Newspaper Clippings about bees are appreciated when sent to us, even if we do not reproduce them in the Bee Journal, or acknowledge their receipt. It helps us to keep informed as to what is being said in the newspapers, and sometimes gives us an opportunity to say something that may be of interest to all.

So we will thank our readers if they will continue to send us clippings of what they find about bees in the newspapers they read.

A Pure Food Law in Each State, with a State inspector to whom any one may send samples of suspected adulteration for analysis, and who shall have full power to prosecute those guilty of adulteration, with fines for first offense and imprisonment for repetition—that is what F. A. Snell, in Gleanings, says is needed.

Southern Honey.—Mr. O. O. Poppleton has had much experience as a bee-keeper in the North and South, and also in Cuba. He says in Gleanings that the honey-region of the North is a comparatively narrow strip with less than a dozen species of flowers yielding honey enough to affect the general markets. A greater variety exists in the South, on account of soil and climate. "One can journey on a railroad train, between sunrise and sunset of any day, and not a single flower that yields honey where he started from in the morning will be found where he is at night," so great is the variation as the tropics are approacht. Florida may be divided into three sections, each having its own kind of honey. A large part of Texas honey differs from all other Southern honey. So it is all over the South, so that no one man knows all the varieties of Southern honey. No one kind predominates in the South, as does clover, linden or buckwheat in the North. The kinds vary from the mildest to the strongest, from the whitest to the blackest, and from extra light in weight to the heaviest.

Central and Northern California are getting enough rainfall, judging from the following paragraph taken from a letter written us by W. A. Pryal, of Alameda county, Jan. 10:

"Our 'dry season' is over; we are having very copious rains. Tho they are bringing the rainfall up to the average in central and northern California, the precipitation is not all that could be desired in the lower counties. Still, I have not the least doubt but that portion of the State will have plenty of rain yet. I trust so, as they need it badly. The rainfall up this way is in excess of what it was for the whole of last season. The mines will again boom; so will farming."

Bees and Flowers. H. W. Brice says in the British Bee Journal:

"What flower show or horticultural fete is now really complete without its bee-department? So much have honey and bees become associated with flowers, fruit and rural festivities, that the first thing sought for by many visitors on such occasions is 'the bee-tent.' This is, of course, as it should be, seeing how dependent one branch of horticulture is upon the other."

It might be a good thing if we could imitate our British brethren in this regard.

A Bear-Proof Apiary is described by "Rambler" in Gleanings, and illustrated. A platform is built about two trees, too high for a bear to reach its edge, and if he attempts to climb one of the trees he merely butts his head against the platform. A movable ladder gives the bee-keeper an easy ascent. About 20 hives are on a platform. Keeping bees on trees is getting almost back to Nature's way!

Comb Honey is reckoned officially at 12 pounds an equivalent of one gallon of extracted, for duty purposes. More or less of the comb honey product comes over the Canadian frontier.

United States Bee-Keepers' Association is the way it will be spoken of hereafter instead of the United States Bee-Keepers' Union. We learn this from General Manager Secor, who wrote us Jan. 14 the following on a postal card:

You can write our name now as "United States Bee-Keepers' ASSOCIATION." The votes coming in indicate that all amendments are carried big.

Mrs. Secor is not up yet, but I am all right. Just closed a \$60,000 deal. How's that for a bee-keeper?

EUGENE SECOR.

We regret to learn that Mrs. Secor is not well, but are very glad that the General Manager is "up and at it again."

It seems to us that a man who can handle a deal involv-

ing \$60,000 is a good deal the kind of a man to have as General Manager of the United States Bee-Keepers' Association, especially as it contemplates dealing with adulterators of honey, and other frauds that threaten bee-keepers or their product.

But perhaps Mr. Secor will not thank us for telling thus publicly one of his private business affairs. And yet, what harm can come from bee-keepers advertising to the world the business capabilities of a man whom they all claim as their own? We contend that Mr. Secor *belongs* to the bee-keeping public, for is he not their valued servant? Most assuredly he is. And one that they all delight to honor, as well as to appreciate his excellent qualities.

Now, Mr. Secor may be inclined to blush at these remarks. All right, for it will be an honest blush, if he does. We believe in giving a few "flowers" to a man before he dies, rather than leave them all for his funeral.

Cuban Honey.—The kinds of honey in Cuba are much fewer in number than in our Southern States. Two-thirds or more of the honey that will come from Cuba will be from bellflower, says Mr. O. O. Poppleton in Gleanings. It is like white clover in color and body, but a trifle milder, selling perhaps better than linden, but not as well as clover. Other Cuban honey is dark and strong, not as good in body or flavor as buckwheat. Editor Root thinks bellflower will compare favorably with our light honey, only some may think it *too* mild. As to Cuban competition, he thinks we will have to grin and bear it, altho he seems to get beyond his depth when he contemplates honey produced for 2 cents a pound, and almost the year round.

COLUMBUS COMMISSION AND STORAGE CO., of Columbus, Ohio, seems to be out of existence now, as we received a card from their postmaster a few days ago telling us that the firm is "Defunct." Our readers will please note this, and not ship any honey to them.

MRS. EMMA WOODMANSEE, of Arapahoe Co., Colo., writing us Jan. 9, said:

"I enjoy reading the American Bee Journal, and look anxiously for its arrival each week. I have learnt a great deal from reading what others write."

MR. WM. H. EAGERTY, of Republic Co., Kans., gives his estimate of the "Old Reliable" in these words:

"I feel that the American Bee Journal deserves the support of every bee-keeper in the land for the stand it took against fraudulent commission-men, thereby saving many hundreds of dollars to bee-keepers."

MR. W. A. RRYAL, of Alameda Co., Calif., writing us Jan. 10, had this to say about the present "new" appearance of the old American Bee Journal:

"I like your new dress. I suppose, like most editors, you put it on the paper instead of on your back. A publisher feels happy when he can come out with a new typographical dress, as well as with a fine suit of clothes. It is almost a standing joke that a newspaper man cannot do both at the same time. I trust, tho, that you have been able to do both."

Well, Mr. Pryal, that depends upon the prices of the "dress" and suit. If the "dress" costs several hundred dollars, then of course the suit would have to be rather in-

expensive. And that is the way it is this time. Little does the average reader know of the cost of getting out a paper like the American Bee Journal *every week*. And yet it is furnished at the very low price of \$1.00 a year. You would hardly believe it, yet there are actually some bee-keepers who write us that if we will take 50 cents a year for it they will subscribe! Such fellows are too cheap to notice. Why, they couldn't appreciate any kind of a bee-paper. And yet, we wouldn't be surprised if such specimens spend annually for tobacco from ten to twenty times the regular subscription price of the American Bee Journal.

But some people always expect to get something for nothing. There is need of cultivating a little more honorable spirit among such folks—a spirit of willingness to pay what a thing is worth. No up-to-date bee-keeper, or one who desires to be up-to-date, would do without the American Bee Journal if the price were \$2.00 a year, as it used to be when it was only a monthly. At least that is what we are often told.

MR. L. D. STILSON, of York, York Co., Nebr., is trying to get a collection of different samples of honey to place in their State University, and wishes to secure samples of Cuban or other foreign honey; also palmetto or cotton-bloom honey, three to five pounds of each kind. Any one who can help Mr. Stilson, will kindly write him before sending him any honey.

MR. MARK DAVIS, a bee-keeper of Dupage Co., Ill., died Jan. 13. Mr. Harry Hatch kindly notified us. Mr. Davis was one of the first bee-keepers of that county. He had kept bees continually for 25 years, and until the last year or two he was regular in attendance at bee-keepers' conventions. He was a member of the Illinois Bee-Keepers' Association. He was 73 years old.

MR. AARON J. JOHNSON, of Monmouth Co., N. J., wrote us Dec. 5, when remitting for 1899:

"I have read copies of the different bee-papers, but the American Bee Journal takes the lead of them all, for me. Different things that I have wisht to learn at times have been answered in the Bee Journal right 'to the t.' I wish it continued success."

THE LEAHY MFG. Co. claim to have "spent about \$5,000 for improvements" in and about their bee-supply factory the past few months. They say: "We expect, too, to take care of the trade; but of this we are not so sure." Well, if they should be unable to "take care of the trade," there are some others that can do it very well—or at least they'll make a big "try" at it.

MR. FRANK McNAY AND WIFE, of Columbia Co., Wis., are spending the winter in Southern California, as announced in these columns some time ago. A letter to us dated Jan. 10, reads as follows:

FRIEND YORK: We have now spent almost six weeks in this land of sunshine and flowers, and have enjoyed it very much, as the weather has been very nice for wheeling, and as we brought our pair of Rambler wheels with us. We find nice, hard roads here, both in the cities and country, and my cyclometer shows 600 miles of travel since arriving here. You can see that we are not losing much time on account of bad weather.

But the lack of rain is making the bee-keepers and all other residents begin to feel gloomy, as the rainfall only aggregates a little over two inches, which is extremely light for this date. Still, there is hope for an abundance yet.

The American Bee Journal is the only publication that has followed us up promptly and regularly.

Truly yours, FRANK McNAY.

We are pleased to know that our big bee-keeping friend, and wife, are having such a nice time this winter. But if California bee-keepers don't get their necessary "wetting" pretty soon, their honey crop will likely be both "short and sweet," when they all hoped it would be "long and sweet" this year. We trust they may yet have rain enough to insure at least an average crop.

The Premiums offered on page 30 are well worth working for. Look at them.

Dilute Honey Before Boiling, in case of boiling foul-broody honey, says Reyne, by adding 25 percent of water. Otherwise the honey will be burnt.

Taylor's Swarming Device is not a success with some, says Editor Holtermann, of the Canadian Bee Journal, because they put the bees in the new hive too soon, before they have time to settle. Let them first settle in a cluster in the catcher, then they will stay quietly where they are put.

How to Rear Giant Queens.—C. T. Bonney uses the Doolittle method of rearing queens and by making cell-cups $\frac{1}{4}$ or $\frac{1}{2}$ larger than common, he has reared the largest and most prolific queens he has ever seen. —Gleanings. But does not Doolittle say that medium-sized queens average better than very large ones?

Comb vs. Extracted Honey. The editor of the Canadian Bee Journal has been doing some figuring. Sections, foundation and shipping-cases are estimated to cost about $2\frac{1}{4}$ cents a section. Deducting this leaves $6\frac{1}{4}$ to $18\frac{1}{4}$ cents a section for Canadian comb honey. Extracted sells within $\frac{1}{4}$ to $2\frac{1}{4}$ cents of this price, and considering the difference in amount obtained, he thinks it does not pay to produce comb honey with the present market difference.

A Good Colony of Bees in Early Spring was some 15 or 20 years ago defined by the New York Bee-Keepers' Association to be a colony with bees clustered in five to seven of the spaces between the combs, the bees nearly touching the sides, bottom, and top of the hive in the center ranges, and at the outside covering a surface as large as the hand, thus occupying four to six combs on a cool morning in the fore-part of April. —G. M. Doolittle, in Progressive Bee-Keeper.

How Long Bees Live on Honey they Can Carry.—M. de Layens put bees in a dark cellar with only what honey they had in their sacs, leaving them in quiet. No extra mortality was shown till the 8th day, when the bees began dying, and would soon have starved if they had not been fed. G. Butet thinks they would not stand it so long under ordinary circumstances, and thinks it wise to feed a new swarm in four or five days after hiving if the weather is such that they can get nothing from outside. Bulletin Bourguignonne.

Bees for Honey. While in a good season the difference in colonies is not so noticeable, the past poor season has brought out a strong contrast, says Harry S. Howe, in Gleanings. Young queens gave best results, especially queens reared after the honey-flow the previous season. He has preferred blacks heretofore because he can work faster with them, but the past season has convinced him that he will get more honey with Italians or Carniolans. W. L. Coggs shall is with him in his change of opinion, and will spend \$50 in the spring for queens to change his stock.

The Honey Harvest and its Signs. In general, wet years are not good honey-years. Those tolerably dry but not too dry are best. Bright sunshine is favorable, if not too dry. Flowers yield most when giving out the strongest fragrance. Especially is this true of buckwheat, which yields no honey when it yields no fragrance. When a good yield is on, the bees start out eagerly early in the morning, the alighting-board is black with bees that drop heavily with their burdens, and in the evening the ventilators are very busily occupied. But the best way of judging as to the gain is by means of weigh-scales. Bulletin Bourguignonne.

Sweet Clover in a Dry Spell was a boon to Thaddeus Smith, as he reports in Gleanings. It afforded his bees good pasturage in a very dry spell in July and August, when there was nothing else for them. He found the honey dark

and unpleasant in taste. A. I. Root thinks there may be some mistake about this, saying he never saw any sweet clover honey that was dark or unpleasant. As a forage crop, Mr. Smith says of it:

"I am pleased with my experiments with sweet clover. Cut when young, and fed to cows, in stall, they ate it greedily. It will bear cutting two or three times or more. I plowed some under in my young peach-orchard, and planted late sweet clover. Turning under such a large amount of tops and roots can't help being beneficial. I am satisfied there will be no trouble to prevent its spreading where I don't wish it—not more than other clovers or weeds."

How Long Shall Foul-Broody Honey be Boiled?—I shall be glad to believe that it is necessary to boil foul-broody honey only "several minutes?" but please remember that we have the following to face, which stands yet as a fact: "Prof. Mackenzie secured growth from spores after they had been kept at 212 degrees—not approaching, but at 212 degrees; that is, they were brought to a boil, and kept boiling for two full hours. If there is no mistake about this, is it safe to advise less than something more than two hours? [The only question in my mind is whether these scientists did not make a mistake; and ought their single scientific experiment to overbalance the results of practical experience for years?—Ed.]—Gleanings.

Winter Apiarian Work. When bees are settled in winter quarters, the next thing to do is to prepare for the coming honey harvest. Repair and clean unoccupied hives, make needed new hives, put foundation in brood-frames (don't worry about its getting old; it is just as good if prepared years before needed), and get all surplus arrangements ready. Such is the advice of G. M. Doolittle, in the American Bee-Keeper. He thinks best to count on 150 pounds of comb or 250 extracted for each colony. Less than this finds him left behind about one year in five. Have bait sections in section supers. Then study over what is to be done the next year, read over again the bee-papers, and write to them some of the new things you have learned in your own experience.

Disadvantages of Large Hives. C. P. Dadant has in a series of articles in Gleanings been giving the arguments in favor of large hives in such strong manner as perhaps no other could do, and having given their good points, he now gives their disadvantages in a manner that is remarkable for its fairness. The large hive costs nearly twice as much as an 8-frame dovetailed. It is not suitable for comb honey unless under special management, for honey will go in the brood-combs that ought to go in the supers, especially in a bad season. It is bulky as well as heavy, needing two men to move it in the apiary, and it is twice as much work to cellar as the smaller hive. The worst thing is transportation. A wagon that will take 28 small hives will take only 12 large ones. Freight on the railroad is twice as much as for the small hives. But in view of the fact that the Dadants do very little moving of hives, the better wintering in the large hives, the less danger of spring dwindling, and the greater scope for a prolific queen, they feel warranted in continuing the use of large hives.

Sectional Hives are a bone of contention between Messrs. Aikin and Doolittle in the Progressive Bee-Keeper. Mr. Aikin makes this pleasant picture of a hive composed of sections 15 inches square and 5 inches deep: "Friends, just look at it. With these sectional hives the apiarist can make increase or not as he pleases, can make any and all colonies work in supers, can cause all (nearly) of the honey to go into supers, can at any time make the size of the hive conform to the needs of the case, whether increase or honey is wanted. You can contract and squeeze white honey to the surplus, and then enlarge and get the dark for winter stores."

Then Mr. Doolittle replies: "I wish to ask him and the readers if they think it will pay to have our bees brooding sticks and empty space, during the spring, instead of queen's eggs, larva and pupa bees? Just sit down and figure how much of that kind of a thing must be done when two sections of his wonderful (?) hive are placed together for a brood-chamber. Do you see that row of bottom-bars clear across the hive? Then all that vacant space between them and the top-bars, necessary for a bee-space? Next, all of those top-bars? Thousands of bees could be reared were this comb with the same economy of heat, etc."

Getting Sections Well Filled.

On page 795 (1898) is a letter about getting all sections well filled. I would like to ask Mr. Harding how he would operate if he were here in Utah. At a suitable place a bee-master can produce from a strong colony, by not letting the bees swarm, from five to nine cases of comb honey in one season. 28 one-pound sections in a case. Where we have here to take comb honey off about every 10 or 12 days, I would like to have Mr. Harding tell through the American Bee Journal how he would manage in a good season, to keep the comb honey from travel-stain. I have been a subscriber to the American Bee Journal since I kept bees in Missouri, years ago, and also when I was in Texas. I have been here four years. I do not see how any one in the bee-business can do without the American Bee Journal, if he wants to be successful. FRIEDRICH SCHMIDT, Salt Lake Co., Utah, Dec. 20.

Good Rain in San Diego Co., Calif.

In this portion of California bee-keepers have had but little to do the past summer in the apiary, except to feed the bees and try to preserve the combs of those that starved out. We had a good rain over most of San Diego county Dec. 16, which revived the hopes of the bee-men, as well as the orange and lemon growers, for many orchards were suffering for irrigation, and no water in the reservoirs for the purpose. All now feel encouraged. Grain is being sown at a great rate, and with continued favors we will be "right side up" the coming season. F. C. WIGGINS, San Diego Co., Calif., Dec. 20.

Poor Year for Bees.

I am well pleased with the American Bee Journal, and think every one who keeps bees should have it. This has been a very poor year for bees in this portion of Texas. The season started out promisingly, the early flowers in full bloom, and hives full of brood; but about the last of March a blizzard came and killed all the brood and flowers. A great many bees died for want of food, and but few swarms issued in consequence in a large section of country. However, where the hives were not robbed too close, there is enough left for wintering; and if we can get an early and mild spring, bees will do well next year. McLennan Co., Tex. A. A. PERRY.

A Turkey Dollar Puns, Etc.

The year is drawing to a close. Another Christmas is near, following quick on the heels of the last. Again I find myself in arrears for the American Bee Journal, and again the dollar allotted for holiday enjoyment must go to Editor York to enable him to dine at Christmas on his annual favorite repast of roast turkey. I don't complain nor envy in the least. Tho I should dine on savory stuff owl, the thought would be compensating, that tho the Editor was regaling on tempting, toothsome, tender turkey, he has each week furnished me with a mental repast far better than any holiday's feasting could be. But I have concluded not to have the Editor draw on me next year for his Christmas feast, so I will play him a little trick, send him two dollars, then he will have to look to some other delinquent subscriber, if he has any, for his turkey dollar.

The American Bee Journal is a good vehicle of information in regard to the changing seasons in various parts of the country, through the reports of bee-keepers which show that no two seasons are exactly alike

SEED DUE BILL FREE

To get new customers to test my seeds I will mail my handsome catalogue for 1899, lithographed and beautifully illustrated, and a 10c. Due Bill, good for one worth of seeds for trial, absolutely free. It is full of bargains. All the Best Seeds, Bulbs, Plants, Roses, new Fruits, Farm Seeds, Potatoes, etc., at lowest prices. Ten Great 50c offers, offered without names. I will pay \$50. FOR A NAME to each. Don't buy your stock until you see this new catalogue. Several varieties show in colors. Great inducements for orders this year. You will be surprised at my bargain offers. Send your address on Postal to-day. Tell your friends to send too. Old customers will receive a copy. F. B. MILLS, Seedman, Box 88, Rose Hill, N. Y. Please mention Bee Journal when writing.

Glass Honey-Jars

For 3 4 Pound at \$3.75 per Gross.

We have on hand a limited supply of tall, straight, white-glass, Honey-Jars, holding 3 4 pound each. They have a tin cap that screws on the glass. They are very attractive for the retail grocery trade. Put up in barrels holding exactly one gross each, to be, Chicago, \$3.75 per gross; 5 gross, \$3.50 per gross. Address,

GEORGE W. YORK & CO., 118 Michigan Street, CHICAGO, ILL.

FREIGHT PAID

to any address. That's the way we send our

CYPHERS INCUBATOR.

It combines the good qualities of all machines and has the faults of none. Our Catalogue and Guide to Poultry Culture tells all about the laws of incubation, and how to raise, feed and market poultry—all about the money end of the business. Contains plans for construction and cost of modern poultry houses and many other things worth knowing. Sent for 10 cts. THE CYPHERS INCUBATOR CO. Box 50, Wayland, N. Y. in the same locality. Probably this immense section of country was never surpassed in honey-producing and bee-increasing during the months of May and June in the same months of any previous year. But since then we have had drouth and dearth, so the bees have a long autumn and winter rest.

Sometime since some one (I have forgotten who) alluded to, as being displeasing to him, Editor York's "horrible puns!" "Horrible?" I thought they were pithy, pointed, pleasing, the spice of composition, and would like the Editor to cultivate his punning faculty. Can our friend, that thinks puns horrible, put words together in a more pleasing style than the following pat, pithy, pointed, pleasing pun attributed to "Bill Nye?" One day, when seated at a hotel table with other guests, the sable waiter approached bearing a turkey on a plate which he accidentally dropt on the floor. Then said Nye:

"Gentlemen, we here see the downfall of Turkey, the upsetting of Greece, the destruction of China, and the humiliation of Africa." J. L. SEXTON.

Sheboygan Co., Wis., Dec. 21.

Got No Surplus Honey.

I have 11 colonies of bees packed for winter on the summer stands. My bees did no good this year. I did not get any surplus honey, and had to feed some colonies, yet this has not discouraged me in the least, for I hope to come out successfully in the end.

I could not think of trying to keep bees without the American Bee Journal. It is a welcome visitor every week.

J. P. PIRKIN, Bollinger Co., Mo., Dec. 21.

Prospects in Southern Clifornia.

As to the prospects of the bee-industry in Southern California, up to this date I never saw it so discouraging. We have had scarcely enough rain so far to lay the dust, and it is now almost January. At this time of year usually the hills and valleys are covered with green, but now nothing but a parched and barren waste is presented to the eye. Unless rain soon comes I don't see how bee-men can hope for much of a return for 1899. A. ROZELL, Los Angeles Co., Calif., Dec. 21.

Has Kept Bees Five Years.

There are many bee-keepers in this part of the State who keep from one to 40 colonies, and are all depending on what they knew 50 years ago in the management of their bees, unless they can steal it from me by borrowing my American Bee Journal and never returning it.

I started in the bee-business five years ago, with two colonies; I now have 80 in fine condition. I winter them on the summer stands, with Hill's device and chaff cushions. My winter losses have not been over 5 percent. I credit my success to "A B C of Bee-Culture," "Langstroth Revised," and the American Bee Journal, which I could not well do without.

Wm. C. HUDNALL, Fulton Co., Ill., Dec. 23.

Recipes Using Honey.

HONEY APPLE CREAM PIE—Line a pie-plate with pie-crust, then pare and core the apples, lay them one piece at a time till the plate is covered, and sprinkle over with flour; then $\frac{1}{2}$ cup of honey and $\frac{1}{2}$ cup of sweet cream; also sprinkle a little cinnamon on, and bake till the apples are done. This is good.

HONEY APPLE SHORT-CAKE.—Pare and core two quarts of apples, boil till half done, then add one cup of extracted honey, and cook till done, then put on short-cake when warm. To be eaten warm. For dough for short-cake, take 1 cup of sour-milk, $\frac{1}{2}$ cup of good cream, pinch of salt,

BEST EXTRACTED HONEY FOR SALE.

ALL IN 60-POUND TIN CANS.

ALFALFA HONEY.

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

BASSWOOD HONEY.

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms in Wisconsin. It has a stronger flavor than Alfalfa, and is greatly preferred by those who like a distinct flavor in their honey.

Prices of either Alfalfa or Basswood Honey:

A sample of either, by mail, 8 cents; samples of both, 12 cents. To pay for package and postage. By freight one 60-pound can, 8 cents a pound; two cans, 7 1/2 cents per pound; four or more cans, 7 1/2 cents per pound. Cash must accompany each order. If ordering two or more cans you can have half of each kind of honey, if you so desire. This is all

ABSOLUTELY PURE BEES' HONEY,

The finest of their kinds produced in this country.

We would suggest that those bee-keepers who did not produce any honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere. "YORK'S HONEY ALMANAC" will be a great help in creating customers for honey. See prices on another page.

teaspoonful of saleratus, and bake in two layers, then spread the above apple sauce between the layers, and on top of the last layer. To be eaten with sweet cream and honey.

HONEY-CAKE.—One cup of honey, 1 cup of cream, 1/2 teaspoonful of saleratus, 1 egg, 1/2 teaspoonful of ginger, pinch of salt; flour.

At present we have 50 colonies of bees on the summer stands, all in chaff hives, and all alive to date. We had 22 young swarms last summer, and 28 old colonies. For this poor season we got 400 pounds of honey from 25 colonies, and the others we think have enough to winter on, or very nearly. We run for comb honey. We have had two weeks of very deep snow, tho not very cold, but now it is thawing.

MR. & MRS. IKA C. MATTESON, Wyoming Co., N. Y., Dec. 21.

An Opinion of Bee Co., Tex.

I believe this is the poorest country (Southwestern Texas) on earth. Too dry; and there is a bug, moth or weevil for everything that grows or lives. Bee-moths are as thick as mosquitoes in the Kankakee swamps. If a bee turns his back at the entrance, in goes a swarm of moths.

Another thing, it costs more to get the honey to market in small quantities than it is worth. If one sells it to a certain firm in this county, he might as well get a tin bill and pick dirt with the chickens.

Bee Co., Tex., Dec. 21. O. H. STEVENS.

Past Season's Report.

Altho I have been in the bee-business only about three years, I feel that I can't get along without the Bee Journal. I had nine colonies, spring count, in 1898, and am wintering 20 colonies. The increase was all by natural swarming. I ran for comb honey, and got about 400 pounds, mostly all from fall flowers.

GEORGE E. KILMER, Cayuga Co., N. Y., Dec. 20.

Report for Two Seasons.

I started in the spring of 1897 with two colonies of bees, and got 90 pounds of comb honey from the two old colonies, and five swarms; so I had seven colonies to put into winter quarters. They came out all right the next spring, and from the seven I got 527 pounds of comb honey, and 16 swarms. I have put into winter quarters 21 colonies, and up to date they are doing finely. The temperature stands at 40 degrees, and has not changed a degree since putting them away. I put them into the cellar Nov. 19.

I am highly pleased with the American Bee Journal, and I attribute my success to it.

FRANK E. KNAPP, Wadena Co., Minn., Dec. 24.

Bees Did Very Poorly.

My bees did very poorly this year. I had 30 colonies, spring count, and got about 125 pounds of honey in all. I have now 33 colonies in fair condition—21 in the cellar and 12 on the summer stands packed in sawdust. But I don't have to depend on bees alone; I have a farm, and have plenty of work. Bees are only a side work with me. There was lots of white clover and Alsike, but it did not furnish any honey to amount to anything the past season. LOUIS THIEL.

Huron Co., Mich., Dec. 26.

A Report for 1898.

My report for 1898 is about 500 pounds of comb and about 300 of extracted honey, from about 250 colonies, spring count, and they are in poor condition for winter. Some probably will starve before spring comes.

I want to tell Dr. Miller that I can hold him level on putting bees into the cellar. I commenced at 9 a.m. and quit at 5 p.m., and put in 234 colonies, all myself, in that

JUST READ WHAT THEY ARE :

Offer No. 1.—Samantha at Saratoga.

100,000 Sold at \$2.50 per copy.

This is indeed a feast of fun, by the only peer of Mark Twain's humor—JOSIAH ALLEN'S WIFE (Marietta Holley.)

Read this Extract from the Book:

And right here, let me insert this one word of wisdom for the special comfort of my set, and yet it is one that may well be laid to heart by the more opposite one. If your partner gets restless and oneasy and maddin' cross, as pard-

ners will be anon or even oftener—start them off on a tower. A tower will in 9 cases out of 10 lift 'em out of their oneasiness, their restlessness and their crossness.

Why I have known a short tower to Slah City or Looontown act like a charm on my partner, when crossness wuz in his mean and snappishness wuz present with him. I have known him to set off with the mean of a lion and come back with the limment of a lamb.

And jest the prospect of a tower ahead is a great help to a woman in rubin' and keepin' a partner straight. Somehow jest the thought of a tower sort of lifts him up in mind, and happy's him, and makes him easier to quell, and partners must be quelled at times, else there would be no hvin' with 'em.

She takes off FOLLIES, FLIRTATIONS, LOW-NECKED DRESSING, DUDES, PUG DOGS, TOBAGGANNING, ETC.

Opinions of Noted Critics:

"Exceedingly amusing."—Rose E. Cleveland. "Delicious Humor."—Will Carleton. "So exuberantly funny, we had to sit back and laugh until the tears came."—Witness. "Unquestionably her best."—Detroit Free Press. "Bitterest satire, coated with the sweetest of exhilarating fun."—Bishop Newman.

Nicely bound in paper, fully illustrated, printed from new type and on fine paper. 370 pages. Postpaid, 40 cents.

Offer No. 2.—Gleason's Horse-Book.

By Prof. Oscar R. Gleason.

This is the only complete and authorized work by America's king of horse trainers, renowned throughout America and recognized by the United States Government as the most expert and successful horseman of the age. The whole work comprising History, Breeding, Training, Breaking, Buying, Feeding, Grooming, Shoeing, Doctoring, Telling Age, and General Care of the Horse. You will know all about a horse after you have read it. No one can fool you on the age of a horse when you have this book. 416 pages, bound in paper, with 173 striking illustrations produced under the direction of the United States Government Veterinary Surgeon. In this book Prof. Gleason has given to the world for the first time his most wonderful methods of training and treating horses. 100,000 sold at \$3.00 each. Our price, postpaid, 40 cents.

Offer No. 3.—The Poultry-Keeper Illustrators.

The four "Poultry-Keeper Illustrators" are the greatest books on poultry subjects ever issued, and are a veritable poultry dictionary, covering the ground so completely that, having these four books, one needs scarcely anything more except "grit" to become a successful poultry-raiser. You cannot get such other books in the whole world, not even for \$50 each, for they do not exist. Were they given in another form and elaborate binding and colored cuts you might think them easily worth \$5 each, but what you want is not elegant printing, and in these we give you the value in information that you can make use of. They have cost much in labor and cash, but you get all this value for almost nothing. We mail the 4 Illustrators for 40 cents.

Illustrator No. 1.—Poultry Houses, Incubators, Brooders, Coops, etc., 25 cents.

Illustrator No. 2.—Artificial Incubation, Raising Chicks, Testing Eggs, etc., 25 cents.

Illustrator No. 3.—Poultry Diseases, Lice, Grapes, Moulting, Egg Eating, etc., 25 cents.

Illustrator No. 4.—Judging Fowls, Description of Breeds, Mating, etc., 25 cents.

Address **GEORGE W. YORK & CO., 118 Michigan St., CHICAGO, ILL.**

time, and brought them eight to ten rods. Now if anybody has beat this time I would like to know it.

I am like the Doctor—whistling up my courage for next year, as I have plenty of empty sections left over from this year.

N. STAININGER.

Cedar Co., Iowa, Nov. 30.

Entirely Satisfied.

I do not believe in filling a letter with fulsome praise, but I will simply say that I am entirely satisfied with the American Bee Journal, and expect to continue taking it as long as I keep bees. S. H. HERRICK, Winnebago Co., Ill., Dec. 22.

Rather Poor Season for Honey.

My bees did rather poor business this season. I had 62 colonies, spring count, and got only 300 pounds of comb and extracted honey, which was of fair quality. I paid

out \$30 for hives and fixtures last spring, and I sold only \$22 worth of honey this fall, after reserving a good supply for our flapjacks this winter.

All colonies seemed to have plenty of honey in October, when I examined them, but when I came to put them in their winter quarters, Nov. 22, I found they had shrunk considerably, and I fear that some of them will not pull through the winter.

Of course, I can't do without the Bee Journal as long as I keep bees, honey or no honey. C. S. FRENCH.

Todd Co., Minn., Dec. 22.

Spraying Fruit-Trees, Etc.

Like unto other bee-papers that I have perused, the American Bee Journal is good. The Omaha convention notes are particularly interesting; all the addresses made by some of the most eminent bee-keepers of the country have been read and duly considered, more particularly "General

Advice to Bee-Keepers," by Mr. Abbott. I was interested in the various discussions, particularly on the hives and sizes of sections. I have notions of my own, yet largely culled from some one else's, but for me to change 4 1/4 open-all-around sections, and the appliances to agree thereto—I could not afford such alterations for the short honey-flows we have here, and still more particularly when fruit-producers lack good judgment in spraying their trees while in full bloom, thereby destroying thousands of my bees as was the case last season.

It is true that last season's honey-flow was almost a failure here, but the killing off of so many bees dwindled the colonies to such a degree that what little nectar there was could not be collected by them. I hardly know what course to pursue the coming spring to keep the strength of my colonies in fruit-blooming time, unless Mr. Secor might make a few suggestions.

My apiary is reduced from 32 colonies to 22, by doubling the weaker ones and fall feeding them. They are in excellent con

THE BEGINNING

and all that lies between that and the end of the poultry business. From the hatching of the chick until it reaches the market, the best methods of hatching, brooding, feeding and marketing of eggs and poultry are contained in our **100 PAGE POULTRY**. It contains 25 pages check full of the things poultry people should know. Cuts of all the leading breeds, incubators, brooders and a full line of poultry supplies. It will help you out of many of the little troubles that arise in brooding poultry. Sent for **10c.** in stamps.

Marshfield Manufacturing Company,

Please mention Bee Journal when writing.

MARSHFIELD, WISCONSIN.

dition for the winter, protected from the cold west, north and northeast winds, the hives all facing the east.

The Bee Journal will be watch with eagerness as to instructions when to spray fruit trees. M. N. SIMON.

Wood Co., Ohio, Dec. 23.

Report for 1898.

My apiary consists of 38 colonies, and I didn't get any honey. White clover was a failure; basswood was of short bloom, lasting only three or four days. I fed one barrel of sugar in September to help winter the bees. Mine are hybrids and Italians, and a few of the Adels. They were very strong and able for duty, if there had been anything for them to do.

SILAS JOHNSON.

Marshall Co., W. Va., Dec. 21.

Another Year of Failure.

Another year has come and gone, and with it another year of failure. But such is life. I still have hopes of something better for 1899.

I began last spring with 70 colonies in fine condition. The spring was all that could be desired, and the bees built up rapidly, owing to the fact that they had an abundance of stores of the previous season's gathering, for they got but very little from the early bloom. Fruit-bloom was quite abundant, but no honey. Fourteen swarms issued during May, and that ended swarming. These were all hived back with the parent colony, so I had no increase. White clover came on early in June, but it was so perfectly destitute of honey that bees paid no attention to it, working in

stead on honey-dew, getting just barely enough of this miserable stuff to keep up natural wear and tear of the colony.

This thing went on until September, when we got nearly enough from golden-rod and other fall flowers to put the bees in fairly good condition for winter, tho I expect to have to feed quite heavily in the spring.

I have 40 colonies in the cellar, and 17 on the summer stands in chaff hives. Those in the cellar seem to be wintering nicely, while those out-doors seem to be dying off fast. Probably the late cold snap was pretty severe on them.

I am going to try the Golden method of producing comb honey on a few colonies next spring, providing we get a paying honey-flow. L. G. REED.

Portage Co., Ohio, Dec. 24.

Death of an Interested Worker.

Sept. 10, 1898, at the age of 24 years, your appreciative reader, my afflicted son, N. F. Murphy, past from this life. He was much interested in bees, and during his work in that way was quite successful, owing, doubtless, to the information gathered from the American Bee Journal.

M. F. MURPHY, SR.

Maury Co., Tenn., Dec. 23.

Honey from Sweet Clover.

My report for 1898 is 1,000 pounds of honey from 20 colonies, spring count. I think I get all of my surplus from sweet clover. It grew from 3 to 7½ feet high. My neighbors got no surplus. They had no clover. A. D. LORD.

Lyon Co., Minn., Dec. 24.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Jan. 9. The trade is not active in comb honey, many of the retail dealers being supplied with sufficient stock to meet demands for some time to come. Prices are quite steady with 13c for best white, off in color, etc., including amber grades, 10c; dark, 9c. Extracted, 66c for white; amber and dark, 59c. Beeswax, 27. R. A. BURNETT & Co.

DETROIT, Jan. 2. No change in supply of honey as to quality, but prices are somewhat lower than last quotations, viz: Fancy white, 13c; No. 1, 12c; dark, 11c; fancy dark and amber, 9c; 11c. Extracted, white, 66c; dark, 59c. Beeswax, 25c to 26c. M. H. HUNY.

INDIANAPOLIS, Jan. 4. Fancy white comb, 12c; No. 1, 10c; 11c. Demand fairly good, dark comb honey is being offered at 8c with almost no demand. Clover and basswood extracted, 6½c to 7c. Beeswax, 26c to 28c. WALTER S. PORTER.

NEW YORK, Jan. 20. Fancy white, 12c; No. 1 white, 10c; amber, 9c; buckwheat and dark, 7c. Extracted in good demand at unchanged prices. Beeswax rather quiet 27c to 28c.

Trade in comb honey is quiet. White is pretty well cleaned up, but there is a large stock of buckwheat, amber and mixt, having accumulated of late, and in order to sell in quantity lots it is necessary to shade quotations.

HILDEBRAND BROS. & SEIGLER, INC.

BOSTON, Jan. 9. Fancy white, 13c; No. 1, 12c; No. 1, 11c; light amber, 9c; 10c; buckwheat, no call. Extracted, white Northern stock, 70c; Southern stock, 66c. Beeswax, 27c.

The demand for honey seems to have dropped out of sight during the holiday season, but now that it is over we hope to see a better call for it. There is abundance of stock on hand and it now looks as if the expected shortage would not materialize. B. V. SCOTT & LEE.

BUFFALO, Jan. 6. Our honey market is very quiet. Finest 1-pound white fancy combs move slow at 12c—often 11c; excellent grades, 9c; 10c, and dark, poor, etc., 6c to 8c. Extracted, 59c to 60c. Beeswax, fancy pure, 28c; dark, etc., 24c to 26c. BATTERSON & Co.

CLEVELAND, Jan. 2. Fancy white, 13c; No. 1 white, 12c; No. 1, 11c; No. 1, 10c; No. 2, 9c; No. 2, 8c; No. 2, 7c; No. 2, 6c; No. 2, 5c. Extracted, white, 7c; amber, 6c; buckwheat, 5c. A. B. WILLIAMS & Co.

MILWAUKEE, Jan. 9. Fancy 1-lb. sections, 12c; No. 1, 11c; No. 1, 10c; No. 1, 9c; No. 1, 8c; No. 1, 7c; No. 1, 6c; No. 1, 5c. Extracted, in barrels, kegs and pails, 65c to 75c; dark, 59c to 53c. Beeswax, 25c to 27c.

The condition of the market is favorable for shipments of honey, especially of best grades, which are in small supply. The sales are moderate, but we are expecting an increased demand and good trade this spring. A. V. BISHOP & Co.

Convention Notice.

Wisconsin. The 15th annual meeting of the Wisconsin State Bee-Keepers' Association will be held Feb. 9 and 10, 1899, in Madison. Many experienced bee-keepers will be there. The following is a part of the program:

- "What to do with Unfinished Sections" John Trimberger, of Clark Co.
- "Working an Apiary for Comb Honey without Increase" H. Lathrop, of Green Co.
- "Short Cuts in Extracting Honey" Frank Minnick, of Sauk Co.
- "Handling and Shipping Extracted Honey" G. W. Wilson, of Vernon Co.
- "Selling Honey" Gustav Gross, of Jefferson Co.
- "Selling Comb Foundation" Aug. Weiss, of Outagamie Co.
- "Advantage of Honey Exhibits" Ed Ochsner, of Sauk Co.
- "Cellar Wintering" A. G. Wilson, of Vernon Co.
- "Benefits in Attending Convention" J. Hoffman, of Green Co.
- "State Foul Brood Report" N. E. France, of Grant Co.
- "Future Prospects of Wisconsin Bee-Keeping" F. Wilcox, of Juneau Co.

As many other State Societies will be in session the same week in Madison, there will be excursion rates to all who take receipts of their railroad tickets. F. WILCOX, Pres., N. E. FRANCE, Sec., Platteville, Wis.

Order Early

There are indications that the demand for SUPPLIES will be very large this season, and everyone should order as early as possible. We have large facilities for manufacturing all kinds of

26 cents Cash paid for Beeswax.

This is a good time to send in your Beeswax. We are paying 26 cents a pound—CASH upon its receipt.

Now, if you want the money PROMPTLY, send us your Beeswax. Impure wax not taken at any price. Address as follows, very plainly,

GEORGE W. YORK & CO.,
118 Michigan Street, CHICAGO, ILL.

Eastern Bee-Keepers!

Seven years ago we started an Apiarian Supply business in NEW YORK CITY, as we saw an opening here. That we made no mistake in this is shown by the large demand for supplies and our constantly increasing trade. Our aim was to furnish supplies promptly. In many cases bee-keepers find the freight on supplies from the Western factories was as much as the cost of the goods. In buying near home you not only save freight, but get your goods much more promptly. We keep several carloads of

Hives, Sections, Foundation, Etc.,

always in stock ready to ship, and the prices will be found RIGHT. We also run two apiaries for honey and sell BEES AND QUEENS. If you expect to use anything in the Apiarian line the coming year, you will do well to send for our Catalogue. We would be pleased to quote you SPECIAL PRICES on what you want, as this is our dull season, and we can afford to sell for small profits. Hives, sections, etc., are made in Wisconsin, where lumber is low, and the best can be had.

Our Special Price on Foundation, Hives and Sections will make you Smile.

Write for it, stating the quantity you can use. DEALERS should write for our 50 discount sheet which is now ready to mail.

I. J. STRINGHAM, 105 Park Place, New York, N. Y.

CONTRIBUTED ARTICLES

No. 3.—The "Golden" Method of Producing Comb Honey Described.

BY J. A. GOLDEN.

(Continued from page 34.)

HAVING in my last article described a new hive and how constructed, I now take pleasure in presenting a remodeled description with an illustration of a remodeled hive, showing the top of the hive and bottom of the super.

Now, if you look at the picture, you will notice a strip has been cut from each top side-body. Take a gauge and mark $\frac{1}{4}$ inch from the top edge of the side-body, and saw down at each end $\frac{1}{4}$ inch, then with a draw-knife shave the $\frac{1}{4}$ space off, and tack the $\frac{1}{8}$ corner strips on the outside ends of the side-body in place of the inside, as in the new hive; then tack the thin boards on the outside, letting the board be even with the side-body at the bottom, and extend as high as the end-board, or as high as the side-board was before you cut the $\frac{1}{4}$ inch off. Thus you see a $\frac{1}{4}$ -inch bee-space is created over the top of the brood-frames, and the $\frac{1}{8}$ space on the outside of the hive proper.

The supers are remodeled the same way, cutting a strip from the top of the super and letting the outside board extend $\frac{1}{4}$ inch, or as high as the side-body before cutting off the $\frac{1}{4}$ inch.

Thus it is a small task to change a hive as made by any factory to the Golden method, and any one desiring can test the Golden method properly.

The super bottom here illustrates the tin or sheet-iron apron that the section slats and separators rest on, and how put on, as previously noted. It also shows the side passage-ways, and clinch end-strips previously mentioned, making the $\frac{1}{4}$ -inch bee-space over the frames and sections when placed on.

Having given a full, plain and complete explanation, accompanied by engravings, of my hive both new and remodeled, and how constructed, in my next I will give a full explanation of my method of manipulation, so that there need be no mistakes by those who may feel disposed to test the Golden method in 1899; and if found wanting in a single feature I represent, discard the method; but if found profitable, follow it and be happy. But before doing so I trust all who can do so will procure a perfect model hive by which to test the method, that no mistakes be made, either in hive or manipulation, from the fact that a combination cannot be explained on paper like seeing the thing itself.

The great problem that has occupied the minds of the bee-keepers of all ages has been, is, and ever will be, how, or by what method, should we as bee-keepers pursue to in-

crease the production of comb honey, and at the same time curtail expenses.

Mr. Benton—one of our best authors on bees and bee-keeping—said in his work on "The Honey-Bee," Chapter VIII, page 75:

"To secure a yield of surplus honey, the part remaining to be done if all goes well, is merely to put the surplus receptacles in place, admit the bees," etc.

Farther on in the article he again says: "But if swarming complications arise, the whole of the bee-keeper's skill and ingenuity may again be called into requisition to keep the forces together, and storing in surplus receptacles."

Thus the skill lies in having the colonies ready for whatever may come, and a force sufficient to store the whole season's surplus in a few days. My practical work for the past four years with the Golden method here given proves Mr. Benton's words to be undisputable facts; yet we as bee-

Top of Hive and Bottom of Super.

keepers want a system that will not only secure a large percent of surplus over former methods, but a system that will curtail expenses, time, and labor, as well.

These are factors that have caused many of our bee-keepers sleepless nights, meditating and formulating plans which, when put into practice, took the wings of the morn-

ing and were found wanting, notwithstanding wonderful progress has been achieved in the foregoing direction, and to this end the method herein described has in all of my experience doubled the amount of surplus per colony over any other method I have practiced, except in isolated cases, while the expense, time and labor were lessened one-half, and often more than one-half. As I have written hundreds of pages explaining my method to bee-keepers the past three years, in the next article I will again give the formula freely.

Morgan Co., Ohio.

(To be continued.)

Cellar-Wintering of Bees—Hints to Beginners.

BY E. S. MILES.

PERHAPS a little of my experience will be of use to "Wisconsin" (see page 758, 1898). I have wintered bees with bottoms on the hives the same as they were in summer, and also with bottoms off. I very much prefer the latter way, for, as Dr. Miller says, it requires too much attention to keep the entrance clear of dead bees when they have only the usual summer entrance. The Doctor's way may be the best of all, but if one does not have his kind of bottom-boards they must do the best they can under the circumstances.

I always take off the bottoms before carrying into the cellar, as I find that, no difference how carefully you handle bees in carrying in, the going from the cold atmosphere outside to the comparatively warm air of the cellar, always rouses the colonies more or less, and when you lift off from the bottom you will lose a good many bees.

While going into the warm air of the cellar with bottoms off will rouse the colony the same, there is nothing for them to crawl onto, and as they are all ready to be quickly set in place, the disturbance is soon over and they settle down.

I like to have the cellar pretty dark, just so I can see to set the hives in place, and for this reason I seldom work at putting them in in the middle of the day.

While this article is too late to be of any use this winter, I think it will pay any beginner to save it till next fall, as it will save him considerable time to know just how to proceed to get the bees in the cellar in the best condition to stand the long confinement.

With the common loose bottom, if the hives are within three or four rods of the cellar, I pry them loose from the bottom-board a day or two before cellar-ing, so they will be perfectly quiet and undisturbed when I go to carry them into the cellar. The distance to raise them from the bottom-board depends on the strength of the colony. If not very strong, like mine were last fall, one only has to raise them enough to slip a nail under each corner; but if real strong, and the combs nearly full of honey, you may have to raise them a half inch or more. If there is a cold wind blowing the bees will the more quickly draw up among the combs and off of the bottom-board.

In extreme cases, as an extra-strong and cross colony, I carry the hive carefully and set it facing north, near the door, the evening before I wish to put it in. They pry it loose from the bottom, and after an hour or two, when they have quieted down again, I raise them some more at the front end so as to get them all off the bottom.

On a still night, with the temperature at zero, I have had hives raised $\frac{1}{4}$ to $\frac{1}{2}$ inch from the bottom, and still have the cluster touch the bottom-board. In such cases I carefully pick up the hive and carry it into the cellar. The loss of a couple dozen bees from such a colony is no damage.

Right here I would like to say that these extra-strong colonies, when wintered in the cellar, seldom are the best when they come out, as they are largely old bees, and die off fast through the winter. I prefer a moderate colony with young queen and plenty of honey for cellar-wintering, every time.

If the hives are more than three or four rods from the cellar, I carry them the same as I do the extra-strong ones, on a cold afternoon, and have them all ready to take in early in the morning. Sometimes I carry in some in the evening if it is moonlight. Have the cellar prepared before hand, by taking an empty hive or super, and level it on four bricks. Fix as many of these as you need, side by side, as close together as necessity requires, then begin at the far corner of your cellar, set in a hive of bees, then take a couple sticks about 2 inches square and as long as the hive is wide, and lay one on top of the hive just set in, at each

end, for the next hive to set on. Pile up this way till the pile is as high as you want it, then begin on the next one.

If I had only four or five hives I would pile them in one pile, as I think they are better off up from the floor.

The advantages of this way of piling, over the way commonly recommended, is that it is easier to fix the stands, and if you happen to make a jar, as you will sometimes, you only jar the pile of hives you are working on, while the other way you jar the whole lot of hives.

Hives arranged as above in a cellar of the proper temperature will need little or no attention through the winter, and the combs and bees will stay perfectly dry and clean.

To take out in the spring, take a bottom-board, lay it on a box or on the cellar floor, set a hive on it, and they are ready to go out.

Tight-bottom hives need top ventilation in the cellar.

If for any reason I wish to leave the bottom on a hive, I put a quilt of muslin over the frames while it is yet warm weather, then when I get them into the cellar I carefully remove the cover and pile in the cellar the same as those with bottoms off.

All work putting bees in the cellar should be done with the greatest care to avoid jars or shaking of the frames. Always carry a hive endwise of the frames, that is, if a Langstroth hive, the entrance should be in front as you carry it.

Crawford Co., Iowa.

Wintering Bees in the Cellar.

BY S. T. PETTIT.

ON page 602 (1898) may be found the following:

"To prevent mold in hives, the editor of *Revue Internationale* says a plan that has proved satisfactory to all who have tried it, is to have an opening at the back as well as front under the hive, allowing the air to pass through. In this country the same object is attained by those who cellar their bees, by having a front entrance two inches deep, or by removing the floor entirely."

I wish to say, if the writer, by the term "this country," means to include Canada, that he is laboring under quite a big mistake. Since the winter 1886-87 I have practiced and advocated providing air-passages through under the hives by placing $\frac{1}{8}$ -inch blocks under the rear ends of the hives. I also elevate the rear end of each about two inches higher than the front end. There is great gain in having the air to pass automatically through under the hive from front to rear. The difference in temperature between hive air and cellar air causes the air to pass so gently and surely through and around the bees and out at the highest opening that the effect is all that can be desired. A good many in Canada are adopting this plan, and those who do not will, so I think, continue to suffer more or less, and you will hear of them using arts of one kind or other to coax their bees upstairs in the comb honey supers.

In the light of my own experience and observation I see it as follows: A hive that depends only upon a large entrance for ventilation has only what is gained by the diffusion, assisted by the efforts of the bees. Now, I presume we all know that cellar air in a cellar filled with bees is a good way off from being pure, and consequently the hive air has only foul cellar air to purify it. Well, it follows that the diffusion will be sluggish, and the cleansing very imperfect; and the bees, feeling the consequent depression, will, in order to effect a change of air, use their wings, and a disquietude and murmuring will tell the attentive bee-keeper that all is not well. But very likely the colonies will pull through, but they cannot be in just the same vigorous condition that they would be if they had been, during the winter, in a perfectly comfortable condition, not feeling the necessity of moving a wing.

It is a good thing at this time of year to examine and study our bees and bee-cellars, and our methods, and take another step forward in our profession. One thing is certain, and that is this, if our bees are noisy there is room for improvement.

I will add that in my cellar the hives set one upon another to the top of the cellar, with a chaff cushion between them, so that the floor of each hive above another is kept warm through the cushion by the heat of the one upon which it sits. In most of the hives the bees lie upon their own warm floor, kept warm by the heat of the bees below them, and, I tell you, it gives me a good deal of pleasure to go through my bee-cellar two or three times a week, candle in hand, and see the dear little "hum-bugs" sleeping resting so comfortably and free from care. I have no anxiety about their safe wintering. With pleasing anticipations I

see the hives booming with bright, healthy bees when springtime shall come again.

"Spring dwindling," "building up bees in spring," "swarming out," "half-comb honey supers," "bait combs," and other devices to coax the bees upstairs, are phrases strongly suggesting defective wintering.

I have experimented in the line of wintering without floors, and the result has not been favorable in my hands.

There is a great deal of imperfect wintering in Canada, and the worst feature is that so many are satisfied.

Ontario, Canada, Jan. 21.

Those Double Brood-Chamber Colonies.

BY FRANK COVERDALE.

THE "double-deckers" referred to on page 805 (1898) proved to be a very interesting study for me during the entire season of 1898. One very prominent feature that cropped out was their determination not to stay in a single-story after being hived. Only one out of the lot could be induced to stay, the persistent ones had to be "scattered among all nations." I guess they thought eight Langstroth frames entirely too small quarters. The one that did go to work did very well. I never had a reasonable amount of success in hiving swarms on eight frames that had emerged from anything larger, so you see I could not apply the contraction plan at swarming-time.

Why did they swarm so? I can't tell, but I think I might make somewhat of a liberal guess, after watching them and their work. Perhaps the surplus of honey all around the brood-nest had something to do with it. The reason I formed this opinion is because when both stories were chock-full, queen-cells were started at once almost invariably, and very little work in any case was done above. Strong 8-frame colonies right by their side completed two cases of sections, and didn't swarm at all. This strengthens and bears me out on what I have of late years begun to believe, that the more honey stored in and around the brood the greater the liability to swarm.

A colony in a brood-chamber filled solid with brood from the bottom and very close to the top-bars will usually do considerable work in sections before swarming, and with a far less liability to swarm at all.

Right here let me say that an apiary all supplied with good, young, prolific queens will do nearly all to bring about the above solid brood-chamber in time, and to a very great extent lessen the chances of swarming and increase the surplus.

For years I used 10 and 8 frame hives side by side, and the former swarmed fully as much. I am fast coming to the conclusion that it is not so much in the size of the brood-chamber as how completely it is filled with brood before the opening of the harvest. Get such a colony started early above, and keep an empty case directly above the brood, and those more complete above it, and so on until the season begins to draw to a close. Fully 50 percent of such colonies, and treated as above, whether on 8, 10, or on 16 frames will not swarm at all, and these last are the ones that just stack up the honey-cases. I have had them standing from three to six cases high with but a few capt on top, but later on nearly all finish.

Suppose a super is placed on a colony like the latter, and the bees allowed to fill it, wouldn't that be somewhat after the fashion of a double-decker filled with brood and honey? and the swarming-fever will be just as sure as with a double-deck that contains a like amount of honey.

As my experience is so limited I think I will let those of further knowledge next occupy the stand.

Before long I will tell just how I safely introduced 50 Southern queens without the loss of one.

Jackson Co., Iowa.

COMB VS. EXTRACTED HONEY.

A Proposed Experiment to Show Comparative Yields.

BY R. C. AIKIN.

IN this article I am to detail plans for experiments, the purpose of the experiments to prove or disprove present accepted theories. I shall first consider that of comb honey vs. extracted.

Take a number of colonies, which number may be greater or less as the apiarist may be prepared to use in the experiment, and divide the lot into two equal parts. The dividing should be very carefully done, and may be accom-

plished in various ways. I cannot recommend the use of less than 8 or 10 colonies in this experiment. The fewer colonies used the greater by far is it necessary to be *very careful in details*. Even with far more care in the work a small number of colonies used will be far less conclusive than a large number.

Select these colonies long before the flow. It is necessary to have them as nearly equal as possible, and to do this we must be intimate with every colony in its career from early spring till the experiment is concluded. Suppose the flow or harvest is to come in June, make the selection of colonies not later than April. See how nearly each is like all the rest in stores, amount of brood and bees, and in age and general characteristics of queens. I feel confident that very frequently the age of the queen has a great influence upon the colony. I should want the queens of about the same age.

Beginning say about the first of April, make and continually keep a close record of each colony. Have this record state the strength of each colony in both bees and brood. Estimate the number of combs the bees can nicely cover, and the number of combs of brood. Do not fall into the error of recording four combs of brood simply because there is brood in four, but each not over half filled. Estimate the brood as to how many *full combs it equals*, and *not* the number of combs containing brood. Apply the same method to the amount of bees and honey. In estimating honey, if a comb should be extra thick and have probably twice the weight of an average one, make your record show the number of combs average. Any practical apiarist knows at a glance about what is an average full comb.

In my regular manipulations through the spring I follow these rules in recording, and the entry is usually made on a scrap of section in the top of the hive—my hives are so constructed that I can so keep the record-board. I have also practiced using book-entries, keeping the hive number in the book. These entries are always in abbreviation. I have a settled rule as to the order of the entry, here is the order: Month, day of month, amount of bees, amount of brood, and amount of honey. Having this as the order *always*, a system of figures serves the purpose as well as a great lot of words.

On April first I probably examine a colony. My record would read something like this: 4-1, 3-2-4. This means bees to cover normally 3 combs, 2 full combs of brood (this brood may be in 3 or 4 combs), and the equivalent to 4 combs of honey. If I clip the queen I mark in addition, "cpd," or for swarming, "smd," etc.

I do not think this all unimportant. It is *very* important that you *know* the condition of every colony in the experiment, else you draw false conclusions, get erroneous ideas, and promulgate false theories. Any apiarist who will bring himself to the details of an experiment like this, will be well repaid in becoming more thorough and expert in his apicultural work.

During the building-up process prior to the harvest, much will depend upon the management of the experiment colonies. I said the queens should be very like in age and general characteristics. The reason for this is that queens of varying ages—especially if some be very young and one aged—the old queen may fail in the midst of the experiment when too late to remedy the trouble, and such a thing would very seriously affect the accuracy of the result. Do not have a failing queen in the experiment.

Having started with colonies well nigh alike, try to keep them equal all the time. Many and many a queen just as good every way as her rivals in the apiary, falls behind because of environments. Previous manipulation or circumstances may have hampered her so that she had less bees to winter, and so would necessarily have a weaker colony to sustain her in the spring and be one to three weeks behind in breeding up through the spring. To avoid this trouble, or rather to remedy it, when one colony seems not able to keep up with the rest, take from the strongest bees and brood to help the weaker, preferably taking *bees* rather than brood. The reason for taking bees is, the queen that is getting behind may not have bees enough to care for brood as fast as she would lay. A very common reason why queens lay sparingly in spring is because there are not bees sufficient to care for the brood. Try to judge of a queen whether she lacks natural vigor or simply needs more workers, and if the latter, give workers; but if the former, give both brood and workers, thus adding vigorous workers equalizing both in numbers and stamina. Keep the colonies equal, and make them enter the harvest equal in numbers, age and vigor.

I shall not discuss in minute details all the little things

in the prior work, as to how each manipulation must be performed, etc, but having pointed out what is necessary to accomplish I leave the rest to the experimenter. Make sure that each colony has an equal chance; if they become unequal *make* them equal in bees, brood, stores, size of hive, and opportunities for work. Be sure to keep a record of *all* that happens to the colony—brood or bees added or taken, whether queen failed or lacked vigor, day and date of everything affecting individual colonies.

At swarming-time comes the greatest difficulty of all. Oh, for absolute control of swarming! We can equalize bees, brood and stores, but we cannot so well control the swarming matter, yet this is important; if they become unequal in a large measure the previous work so far as accuracy in results is concerned. If one colony swarms, all the others should do so, and do it at the same time. I see no way out of this difficulty save to simply forestall *all* swarming, or, instead, cause *all* to swarm, and on or near even date. A part run for comb and a part for extracted makes it harder to manage. The comb-honey colonies will be almost sure to swarm, while few, or possibly not any, of those run for extracted would do so.

As for myself, I think I would unqueen and control swarming that way: but for those who may have a fall flow it would not do to unqueen in the early flow if the colony was expected to do good work in the late season. I think I should recommend unqueening for those who have but one comparatively short flow, and those having two flows, or one very long one of eight weeks or more, to introduce cells into each of the colonies, doing so just as they are likely to begin cell-building in any of the colonies, and give all alike and at the same time. The cells introduced should be unsealed, and perhaps two or three to each colony, for if given sealed some might not be willing to accept. I think unsealed cells especially three or four days before sealing age would be almost certain of acceptance, and also almost sure to cause swarming.

The fact that swarming makes a difference in the honey-gathering work, first by time lost at *swarming-time*, and, second, by causing the swarm to build comb where ready-made combs are not supplied, would make comparative results very unsatisfactory indeed as a basis upon which to build. It is imperative that in every single test the colonies *must* be alike in every way, or nearly so. Better that many apiarists simultaneously perform these experiments, each upon a few colonies more or less as he may be able, and each do a thorough job. Ten apiarists in as many locations, and each using 10 colonies, 5 to each side, would give us 100 colonies in the test, and in varied conditions. I hope that 20 or 30 at least will take up the work and join me in experimenting.

In my next article I will continue detailing other experiments. Meanwhile I would be glad to receive postal cards from any apiarists willing to help. I expect each to keep a record of the work showing in detail how it was done and the results, and a copy of the record sent to me. After receiving these reports I will compile the whole and place the same before the readers of this journal. It will help all beekeepers, and, most of all, we who do the work.

Loveland, Colo.

Value of Bees to Fruit—Other Items.

BY H. S. PRICE.

I HAVE noticed the Editor's kind invitation for subscribers to write their experience with bees, the way they have them packed for winter, etc., and I thought ere this I would have written my experience. I rather expect, tho, next winter I will be better able to give an account of myself (or rather the bees), as last season was a very poor one for bees, and for fruit, too. Poor for fruit because we had so much rain that the bees could not get to the orchards to fertilize the blossoms. There was plenty of bloom, but it requires something besides just the mere bloom to make fruit—it must be fertilized.

We had one or two nice days during pear and cherry bloom, and the bees got to work on them, so we had a nice crop of each, but the apple crop was a failure. This is quite a fruit country, apples being the main crop, and when we have a failure in apples it means almost a failure in everything else.

I do not want to leave the impression that apples are all that is raised here, where everything grows in abundance, but we feel a failure in apples, I think, worse than anything else.

I have the management of the Plunkett Hill Fruit Farm

at this place, and I sold, last season, \$16.25 worth of fruit. It should have been that many hundred dollars, but the rain kept the bees in so they could not fertilize the blossoms, so we had only "a drop in the bucket."

I was the only one that had any fruit to sell in this section of the country, and if it were not for my bees I don't think I would have had 16 cents worth of fruit. I am, as you will see, a firm believer in my bees.

I have two reasons for keeping bees—pleasure and profit. Pleasure is derived from working with them, and watching them work; profit from the honey and the pollenization of the fruit. I have 24 colonies, all in modern hives. I expect to increase to 50 next season. Last season was my first in this section of the State. I know of no reason why bees will not pay, and pay big, for the extra work they may cause any one here.

We had bees at home (southeastern Missouri), and they paid there, and I think this a much better country for honey than that. The main things here for honey are fruits, linden, white clover, smartweed and Spanish-needle (commonly called "yellow blossom"). The latter is the most productive of all. In the fall there are thousands of acres of it here—it just looks like fields of gold. It lasts about four weeks, and the flow is surely great. It brings to mind the poet who wrote—

"Full many a gem of purest ray serene,
The dark unfathomed caves of ocean bear;
Full many a flower is born to blush unseen,
And waste its sweetness on the desert air."

There are acres and acres of it that bees never get to sip the nectar from a single blossom, there being no necessity for them going far from home—they have all they can do right at their door.

I have the 5-banded Italians to gather honey for me. I think they are by far the best bees. All those who want hybrids can have them, but I want the pure Italians. I think they are better workers, easily handled, and so much prettier than the hybrid or black bees.

I will sometime in the future write an article on the hive I use, and why.
Livingston Co., Mo.

CONVENTION PROCEEDINGS

Proceedings of the Colorado State Bee-Keepers' Convention.

(CONTRIBUTED BY THE SECRETARY.)

[Continued from page 55.]

The President's Annual Address.

Another year has past, and we are again in annual session of our Association. I am glad to meet you, and rejoice that we have had a reasonably prosperous year. True, we cannot boast of large crops, yet there has been a decided improvement over the past few seasons. So far as I have had reports from the various parts of the State, our general crop has been a fair one, and when compared with the average of the States we have no reason to complain. The failure in other States has redounded to our advantage by making a market for what crop we have.

We have reason to rejoice in the fact that our Association now numbers a membership of some 150, the largest membership ever attained. This growth is very encouraging, for it betokens a better condition of bee-culture in all parts of the State.

What has caused this increase of membership and general interest? Let me say to you, *no*%. I do not want to seem personal nor a flatterer, but I do want the members of this Association to know that our very worthy Secretary, Mr. Frank Rauchfuss, has performed a labor of love. He has been untiring and unselfish in his labors in guarding and furthering the interests of this Association and the whole apicultural interests of this State. Your Executive Board and the general committees have worked together to make our Association second to none—not even the National.

Editor York, of the American Bee Journal, has very materially assisted in our work, and this Association is under obligation to him, which obligation I hope will be faith-

fully discharged. In a recent letter from Mr. York, he says that he always looks forward with much interest to the publication of the proceedings of this Association, and that he ranks it next to the National association reports, and expresses a desire that the report of this meeting be sent in to appear in his journal.

Colorado apiarists are lookt up to, and so is our product. I say this not to boast, but for our encouragement. Instead of being puffed up let us rather be humbled, remembering that to whom much is given of the same much is required.

It is my sincere desire that this Association shall continue to grow in both membership and influence, until every apiarist in the State shall be enrolled as a member, and until there shall be a full and harmonious co-operation in the conduct of all our apicultural affairs.

Why do I desire this general interest—why encourage others to success when it is so hard now to find a market for our product? Know you not that freedom is and has been the foundation-stone—yea, is at the very bottom of our national prosperity? Could I monopolize the honey-production of this State, I should thereby temporarily advance my own financial interests, but in my doing so I should necessarily impoverish each of you as producers, and it is common-sense and the soundest of reason that to impoverish ninety-nine one-hundredths of the bee-keepers of our State not only affects these same bee-keepers, but many others in other pursuits as well, and eventually my monopolizing folly comes back as a curse on my own head. My product must sell if I continue to prosper, and only a prosperous people can buy my product. Were it not for the equalizing effects of panics and hard times we would, as a business community, quickly become slaves to the greedy, and soon the whole mass go down to one common grave.

Yes, your prosperity means mine, and I want you to prosper. The growth of this Association means that you will be aided to prosperity. I say you will be aided, for this Association cannot bring you prosperity against all other influences, but it can help. A large membership means more money to do the work of the Association. I want to call your attention to the fact that not one of us knows the burden and expense that is upon our Secretary in keeping the books of this Association, and in correspondence, and the time given to thought in solving the problems that are for our interests, and yet it has been freely given. I desire to see, this year, this Association grow to a membership of many hundreds, and a treasury of hundreds, and that out of that treasury our official servant, the Secretary, get an allowance that will justify him in working for our interests. This would be proper, just and right.

Shall we make the effort, or shall we not? Who will volunteer to do missionary work in the various parts of the State? I commend to this Association the plan of getting some good member in each location to "missionate" in getting members. I shall charge upon my successor to see that the will of this Association be carried out, and upon the members that they rustle and help in both money and work. If each one who is now a member shall get, during the next year, as many new members as has your humble servant during the past year, our next annual meeting should see on our roll near 1,000 names.

I am not offering any visionary scheme, but a business proposition that can be carried out if we put ourselves to the task. I ask that before we adjourn from this meeting we shall each pledge ourselves to the work, and begin the action that shall see not less than 500 stubs on the Secretary's membership receipt book.

R. C. AIKIN.

A discussion then ensued on giving the Secretary a compensation. All were in favor of the idea, but as the condition of the treasury did not justify it, the matter had to be dropped. A motion was made to confer a loving cup upon the Secretary as a token of gratitude, but at his urgent request it was withdrawn.

The Secretary then made a verbal report of the work during the year, mentioning in particular the soliciting of new members, which resulted in a total membership of 154; the efforts made to create a marketing organization, and concluding with a statement of expenses and receipts.

A vote of thanks was then extended to Prof. Gillette, and he was made an honorary member for next year.

A DISCUSSION ON FOUL BROOD.

Mr. M. A. Gill had been down on the program for an address on foul brood, but had concluded to leave it to Mr. Foster. Mr. Gill said he had been inspector for three years in one locality where there was a great deal of foul brood, but it had been confined to that region by a sort of quaran-

tine, bee-keepers agreeing not to buy or ship out from there. Mr. Foster spoke of the unwillingness of the Boulder county commissioners to pay for the work done.

Mr. Gill If any work is done, a good deal is done gratuitously. If five bee-keepers in the county think the disease exists, an inspector can be appointed; and, if appointed, his compensation must be allowed under the statute. From my experience on the Western Slope, I would not advise any one to use a hive again which has not been disinfected.

Mr. Foster Mr. Adams has more than he can do in Boulder county. He is expected to oversee 18,000 colonies.

Mr. Foster then exhibited a map of the vicinity of Boulder, comprising an area of about six by eight miles, with a large number of locations marked where foul brood exists, and stated how many cases were in each yard. One apiary had about 70 colonies infected out of a total of 140. There are not over two persons in the territory mapped who will send for an inspector. They are careless and indifferent.

H. Rauchfuss—A provision in the law says the inspector has to go where he knows foul brood exists.

J. E. Lyon—Does the inspector have to go when called on?

Mr. Gill He does.

Pres. Aikin—Section 3 of the law says: "Every bee-keeper or other person who shall be aware of the existence of foul brood, either in his own apiary or elsewhere, shall immediately notify the County Inspector of Bees, if there be one, and if not the Secretary of the Colorado State Bee-Keepers' Association, of the existence of such disease, and in default of so doing shall on summary conviction before a Justice of the Peace, be liable to a fine of \$5 and costs." Section 4 says: "On receiving notice from any source, in any apiary in his county, of the disease known as foul brood, or any other infections or contagious disease of bees, the County Inspector of Bees shall forthwith inspect each colony of bees and all hives."

Mr. Adams—Suppose a man comes to me and orders me to inspect when it is freezing hard.

Mr. Martin—Is there any penalty if the inspector does not do his duty?

Mr. Gill—After the inspector has been notified he is amenable to the law as well as the owner. On the Western Slope men watch me to find out any delinquency.

Mr. Lyon I have asked Mr. Adams to go half-a-dozen times. Am I the man to ask him to go in freezing weather? Suppose it is freezing. Let us wipe out the inspector if he is no good. If he refused to go when it was too cold, why did he not go when the weather was favorable? We are overrun by foul brood. I do not mean to be personal.

Mr. Adams I understand that. That is all right. But every one of the days that Mr. Lyon came, the wind was blowing from the north, and it was cold.

Pres. Aikin This is simply a difference in judgment between two men. That point of the proper time was overlooked in the law. If particular colonies are known to be diseased, then any time will do. But whoever formulated the law didn't think of that.

L. Booth—The law is all right. The official is not expected to do his duty at an unreasonable time, but within a reasonable time and in a reasonable manner.

Pres. Aikin You are correct.

Mr. Gill—The time of visit is usually agreed upon between the owner and the inspector. Usually there is no brood in the hives at the time referred to. The best time to inspect is when bees fly freely. I have inspected 3,100 colonies without a veil. There is always some time between June and January to inspect. One man can order the inspector to go to any part of the county.

Pres. Aikin The law does not contemplate the unreasonable, but the point might be brought up whether a certain course is reasonable or unreasonable.

Mr. Foster Early last spring I sent for Mr. Adams. He said the weather was not fit. I put up a tent and a stove, and he came. I think Mr. Adams does well with 18,000 colonies. At every sixth or seventh house, one sees bees. If he stops at every house he spends half his time calling. If he does not, he misses a good many. I say, take a small district and do it well.

Mr. Gill Wisconsin claims the best law. One inspector does it all. The work can be thoroughly done. One inspector can find all the bees diseased. If I found no disease, I spent little time.

Mr. Honnett—Assessors make a list of products not taxed. They could add bees, and the inspector could get his information from them.

Mr. Adams—When my commissioners say, "You've got

to keep down the expenses," I haven't got the money to fight Boulder county and support myself and family.

Mr. Gill—And somebody else says to confine the inspector to \$200 expenses but the commissioners can't go against the law.

Mr. Rhodes—They do in some counties, but it is not the law that they should.

Mr. Adams—I'm hunting the man who gets \$200.

Pres. Aikin—I have here some samples of combs infected with foul brood in an advanced stage after it has dried up. There is another disease like foul brood, and the test is the elasticity of the matter. But the dead brown matter at the bottom of the cells is a pretty good indication.

The samples referred to were put up in a securely enclosed box of glass and wood, the glass being on both sides, next to the faces of the combs.

The reading of the Inspectors' Reports followed, which are here put together and tabulated:

| INSPECTOR. | COUNTY. | Colonies Inspected. | Colonies Destroyed. | Colonies Transferred. | Colonies Destroyed. |
|------------------------|-------------|---------------------|---------------------|-----------------------|---------------------|
| M. A. Gill..... | Mesa..... | 2,921 | 69 | 49 | 20 |
| R. C. Aikin..... | Larimer.... | 47 | 3 | 1 | |
| Chas. Adams..... | Weld..... | 37 | 7 | 3 | 4 |
| Mrs. A. J. Barber..... | Montezuma | 203 | 20 | 17 | 3 |
| J. B. Adams..... | Boulder.... | 543 | 110 | | |
| D. S. Jenkins..... | Bent..... | 64 | | | |
| Peter Kranz..... | Otero..... | 586 | 9 | | |
| T. A. Riggs..... | Arapahoe.. | 484 | 15 | 10 | 4 |
| Significant totals, | | 4,885 | 233 | 80 | 31 |

During the last season there was no inspector in Jefferson county.

Mr. Gill added to his report these remarks: "The disease is still confined to one locality in the county, namely about Fruita. Thorough work has been done in this locality, but the infection seems to be among the wild bees of the community, so that nothing but eternal vigilance will ever stamp it out there; however, people in that section seem desirous to rid themselves of the pest, and are ever ready to assist in stamping out the disease."

Mr. Aikin also reported for his county that six hives where bees had died were ordered treated.

Mr. Jenkins, of Bent county, reported that he had only inspected for foul brood, and found none; but there is considerable paralysis, tho only a few serious cases.

The Treasurer's report was read and accepted, and also the following

REPORT OF COMMITTEE ON PERMANENT HONEY EXHIBITS.

Your committee would most respectfully report that we visited the Board of Capitol Managers, and made known our wishes as to a place in the building and a suitable case to make our permanent exhibit. We were courteously received, and assured that we could have the space and the receptacle.

Owing to some personal influence of which the committee do not wish to speak at present, all of our work has been of no avail.

Committee: J. H. RHODES, H. RAUCHEFUSS,
J. B. ADAMS, J. E. LYON.

(Continued next week.)

York's Honey Almanac is a neat little 32-page pamphlet especially gotten up with a view to create a demand for honey among should-be consumers. Aside from the Almanac pages, the forepart of the pamphlet was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample for a stamp; 25 copies for 40 cents; 50 for 60 cents; 100 for \$1.00; 250 for \$2.25; 500 for \$4.00. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, *Marengo, Ill.*

(Questions may be mailed to the Bee Journal, or to Dr. Miller direct.)

Moving Bees a Short Distance to Winter.

Most bee-keepers winter their bees on the summer stands in this locality, but I always give mine some protection and generally move them to a sheltered place. I dig into a bank just enough to level the place for the hives, and set a row of hives on a 2x4 edgewise, and if the bank is high enough I put another tier of hives on top.

I move some of the hives from 30 to 200 feet from the summer stands to winter quarters, and our bees have a flight every few days all winter. Of course, some of them get muddled up in the first flight that they have, by being moved so short a distance. Do you think it is an error to move them?

NEBRASKA.

ANSWER.—The mixing up of a few bees will make little difference, for what one colony loses another will gain. If there is a great deal of excitement it sometimes happens that a hive may be almost entirely deserted, and of course that's bad. There is a possibility, too, that the presence of a lot of strange bees may endanger the life of the queen, but as a rule I think you will find little loss from either cause. To help hold each colony to its own hive, it may do some good to put a board up close before the entrance, so the bees can get out only by going around the board.

Question on Contraction.

In contracting a 10-frame brood-chamber, say to seven frames, will the bees be likely to build combs to the bottom of the section-holders?

NEW JERSEY.

ANSWER.—The simple fact of contracting from 10 to 7 frames would probably have little to do in the matter. In either case, with plenty of super room and proper spaces between brood-chamber and super, you will have a minimum of bur-combs, while you will be likely to be troubled with them in either case if the bees are badly crowded for room.

Splints to Prevent Foundation Sagging Spacing Frames, Etc.

1. What is your method of using wood splints for preventing sagging of foundation in brood-frames?

2. Will foundation cut to fill the frames, as you use it, cost more per pound than the regular size sent out?

3. I am using Hoffman frames, but intend hereafter to make my own frames, and use staples for spacers, as the Hoffmans are badly propolized. I notice on page 7 you recommend this style to "Illinois." Would you advise me to change the Hoffmans that I have? I can do this without much trouble, by sawing off the projection of the end-bars and substituting staples.

4. If I do this, the staple will have to project 5-10 inch, since the top-bars are only 1-1/2 inch. Now, I wish to make my top-bars 1 1/2-inch, staple projecting 1/2-inch. When two of these frames with top-bars of different width come together, they will be 1-1/2 nearer at one end than at the other. Will this give trouble?

5. What is the best style of queen-excluder to use when hiving swarms on starters?

6. Why cannot the Root zinc be used in making the honey-board composed of alternate strips of wood and zinc?

7. If you recommend this style, please describe it so that I can make it.

NORTH CAROLINA.

ANSWERS.—1. The splints or little sticks are 1-1/2 square, and 1/2-inch shorter than the depth of the frame, inside measure. The paraphernalia needed to do the work are: A pair of pliers to lift the sticks out of the melted wax; a board to use as a presser, 1/2-inch shorter than the inside depth of the frame; three or four inches wide and 1/4 or 3/8-inch thick, with one edge kept well soaked in water so the wax will not stick to it, and a board 7/8-inch thick just large enough to slip loosely inside the frame, having strips nailed

on the sides as stops so that the foundation will rest on the board while the frame rests on the stops. Put a bunch of the sticks in the heated wax. They will froth up at first because of the air and moisture in the wood. In a little while that will be cooked out and the wax will settle down clear. Then with the pliers lift a stick out of the wax and lay it on the foundation, and with the wet edge of the presser press it into the foundation. Being hot it will melt its way into the foundation, and if prest too hard or too long may cut the foundation in two. A little experience will enable you to do it right. It is perhaps well to heat the wax little more than enough to keep it melted, for if too hot there will not be so good a coating of wax on it, and if you use a stick not coated with wax at all the bees will dig out the stick. The sticks are put perpendicularly, one about an inch from each end, one in the middle and one on each side of the middle one-half way between it and the end one.

2. No.
3. Yes, where propolis is at all plenty.
4. I don't believe it would make any serious trouble.
5. Probably the wood-zinc.
6. It can.
7. Make your wood-strips about 5-16 thick, an inch wide or less, having a saw-kerf in each edge to receive the zinc. Put together so that your honey-board shall be flat on one side and the other side shall have the ends and sides 1/4 thicker than the rest. That will make a bee-space between the honey-board and the super.

Getting an Italian Queen Early.

Where can I get a good, cheap, Italian queen? I want one as early as I can get it. I think I could introduce it in March, or April at least. I got a colony of black bees last spring, but they didn't do well. It wasn't a good honey year, but there is an Italian colony right by the side of mine which gathered enough honey to nearly winter, and they are about twice as strong. They were started the same time. I got one colony a year ago, and divided it, but in the fall one of them left, and in February the other died, so I had to get another colony last spring. I intend to keep on, all the same, and make a bee-keeper of myself. The American Bee Journal is the only help I have, but it has been enough so far.

MARY.

ANSWER.—Yes, you might introduce a queen in March or even in February, but all things considered it is not advisable. You'll be as well off if you get your queen in May, probably, running less risk in shipping, and by the time it will be advisable to get a queen you will see queens advertised by reliable dealers in this paper.

Alfalfa or Lucern Van Deusen Self-Spacing Frames.

1. I have read much in the American Bee Journal of alfalfa being so good a honey-plant in the West, but the bees do not tackle alfalfa in the Northern States or gather honey from it. I was born in Germany, and can remember that almost every farmer had a lucern (alfalfa) field. Twelve years ago I ordered some lucern seed from Milwaukee. I noticed in the catalog that German lucern was priced differently from American alfalfa or sand lucern, so I think there must be a difference between lucern and alfalfa, for the bees do not visit my lucern.

2. Years ago I used the common hanging frames, but having much trouble with spacing and getting straight combs, I asked a supply dealer for a self-spacing frame. He showed me one which he called the Van Deusen. This spaced above and below, by means of little irons fastened on each corner. This frame suits me best of all. I have seen the Hoffman but would not want it. The bees cannot fasten the Van Deusen frame to the hive. What is the reason we do not hear anything in regard to this frame? and why do bee-keepers not recommend it? MICHIGAN.

ANSWERS. 1. It is likely that the difference is not in kind but in place. In this region I never saw bees on alfalfa, altho it is the same as that farther west. It is not uncommon for an imported article to differ in price from the home product, even when just the same. Bokhara clover seed is imported into this country and sells at a different price from that of sweet clover seed, altho Bokhara and sweet clover are one and the same thing.

2. The Van Deusen spacers have been before the public for some years. Some agree with you in liking them, while

others prefer the Hoffman or something else. I know of no special reason why more is not said about them, or why they are not recommended more, unless it be that a larger number have not preferred them.

Leveling Down Combs.

What kind of an instrument is used in leveling drawn combs in sections? I understand the cells should not be over 3/8-inch in depth when the super is first put on. I cannot understand why it is not just as necessary to level down the cells of the extracting-combs after they have been completed in the extractor. If good honey can be obtained by leaving full-depth cells in the extracting-chamber, why not leave deep cells in the super combs? MASS.

ANSWER. Taylor's comb-leveler is the tool. It costs \$1.00, postpaid, \$1.25. The object in leveling is to cut away the edge of the comb that has become darkened. That will explain to you why it is necessary to level sections and not

The Taylor Comb-Leveler.

extracting-combs. The comb of the extracting-combs is not taken with the honey, hence there's no need to cut any of it away. Indeed, in most cases it would do no good, for you'd have to cut away all the comb to get rid of the dark part.

Some have insisted strenuously that the comb of sections should be leveled to 3/8 of an inch. I don't believe there ever was any good reason for that, and I have always held that all the leveling that was needed was to get rid of the darkened part. If the comb is pure white clear out to the edges of the cells, there's no need to cut any away, unless in rare cases in which the cells are so deep that they would be built fast to the separator. I think this view is now held by those who have insisted most strongly on the 3/8-inch.

Preventing After-Swarming.

I see by some of the bee-papers that one of the methods to prevent after-swarming is to place the primary swarm on the stand of the old hive, and remove the latter to a new location. It has also been found advisable to give the surplus cases to the new swarm. Now, in removing the surplus cases from the parent colony, is it best to rid them of bees before they are placed on the hive containing the new swarm, or should the supers be lifted off with the bees in them? MASSACHUSETTS.

ANSWER. In taking the supers from the mother colony to give to the swarm, take bees and all. It's easier, and it's better. But if you do this when the swarm is first hived, there is danger that the queen may take up her abode in the supers unless barred by a queen-excluder. If no queen-excluder is used, better wait a day or two before putting the supers over the swarm. To make the plan more effective, it is better to put the old close beside the new one, and in about a week move the old hive to a new place.

Entered at the Post-Office at Chicago as Second-Class Mail Matter.

United States Bee-Keepers' Association.

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE: Pres., E. Whitcomb; Vice-Pres., C. A. Hatch; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS: E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GEN'L MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

VOL. 39. FEBRUARY 2, 1899. NO. 5.

NOTE.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

Journalistic Courtesy.—The editor of Gleanings says he subscribes to the statement we made some time ago, that apiarian editors should give more attention to the matter of journalistic courtesy than has apparently been done within the past few months.

The Constitutional Amendments voted upon by the United States Bee-Keepers' Union were all carried, and almost unanimously, as follows:

First Proposition—To change the word "Union" in its name to "Association."

Second Proposition—Fixing January 1 as the time when the President, Vice-President and Secretary shall assume their respective offices, having been elected at the annual meeting preceding that date.

Third Proposition—Making it the duty of the Treasurer to give 30 days' notice of expiration of membership.

The foregoing amendments were recommended by the convention at Omaha last September.

By the way, on page 633 of the Bee Journal for 1896, will be found a sample constitution that we were requested to submit for consideration, in which Art. I reads thus:

"This organization shall be known as the 'United States Bee-Keepers' Association.'"

So, after all, at least that much of our proposed constitution is now in force. And it is all right. We tried at the Lincoln, Nebr., convention to keep the word "Association" in the name when the present constitution was adopted, but failed.

Philadelphia in Contemplation.—Last week we received this from Dr. A. B. Mason, Secretary of the United States Bee-Keepers' Association:

EDITOR AMERICAN BEE JOURNAL:—The following will explain itself. I have replied to it on behalf of the Association.
A. B. MASON.

PHILADELPHIA, Pa., Jan. 16, 1899.

DR. A. B. MASON

Sec. U. S. Bee-Keepers' Association.

Dear Sir: It affords me much pleasure to inform you that the following preamble and resolution were adopted at the last meeting of the Philadelphia Bee-Keepers' Association, held on Jan. 14:

WHEREAS, We have been informed that the United States Bee-Keepers' Association contemplate holding their next convention in Philadelphia.

RESOLVED, That we send greeting to the United States Bee-Keepers' Association, expressing our pleasure at having them meet with us here.

Fraternally yours,

F. HAHMAN,

Sec. Philadelphia Bee-Keepers' Association.

We understand that the Philadelphia Bee-Keepers' Association is one of the best of its kind in existence, having upward of 40 hustling members. And we believe they would take excellent care of the National convention of bee-keepers should the Executive Committee decide to hold the next meeting in Philadelphia. Personally, that is our choice, but this time we have nothing to say as to the place of meeting. We had our "say" the past two years, and we know that, aside from the lodging inconveniences at Buffalo, it was a splendid thing to go with the Grand Army of the Republic. As Philadelphia is where that great organization, with its low railroad rates, meets this year, we hope the convention of the United States Bee-Keepers' Association will also be held there at the same time.

Honey in Barrels. Sommambulist formerly was in accord with O. O. Poppleton in favoring barrels for extracted honey. He gives in the Progressive Bee-Keeper a pitiful tale—albeit related in Sommy's amusing manner—of an experience which made him take to the fence, "with a most decided tendency to the other side." Eight barrels were kept over one year for a better price, but the contents of those barrels were not satisfied with their quarters, and started out on their travels, resulting in a loss of three barrels from the market, altho some of the honey was gathered up for feeding. One barrel that was waxt proved faithless like the rest. But he thinks honey is improved by standing in open barrels exposed to the action of the air for some time before it is put into cans.

Workers Reared in Drone-Cells. A. A. Astor reports in Revue Internationale something that the editor says he has never seen—workers reared in drone-cells. A good many years ago, R. R. Murphy sent to the office of the American Bee Journal a piece of drone-comb from which young workers were emerging. They did not appear different in any way from ordinary workers.

The Gold Honey-Package has been hinted at in the Canadian Bee Journal, without a description being given. D. W. Heise says it embraces every important feature of a cheap and convenient package for honey, except that it is doubtful whether it will stand enough heat in water to liquefy honey. But why don't our northern friends tell us what it is made of?

Illinois Pure Food Association. Some time ago we called attention to a meeting to be held in Champaign, Ill., Dec. 13, in the interest of pure food legislation. As a result of that conference, the Illinois Pure Food, Drug and Seed Association was organized, and a permanent organization was effected the following officers being elected: President,

A. P. Grout, of Winchester; Vice-President, H. Augustine, of Normal; Secretary and Treasurer, H. S. Grindley, of the University of Illinois. An Executive Committee, composed of prominent representatives of a number of State organizations interested in the subject of foods, was elected. We notice that Mr. Jas. A. Stone, Secretary of the Illinois State Bee-Keepers' Association, is a member of the committee. The conference adopted the following resolutions:

RESOLVED, That it is the sense of this Conference that a bill should be enacted into law which should prevent the sale of articles of food and drugs in Illinois which are harmful to the consumer, and which will also regulate the sale of mixed products under proper regulations, to the end that the health of the people may be protected from injurious products of manufacture, and that mixed products shall not be put upon the consumer in lieu of the higher priced genuine article. Said bill is to include also the regulations regarding the sale of farm and garden seeds.

RESOLVED, FURTHER, That we believe it necessary that a State Commissioner or Commission should be appointed to carry out the provisions of the law.

RESOLVED, That the Executive Committee is hereby instructed to secure the cooperation of all persons and associations interested to assist in the carrying forward of this work, and that the committee be authorized to draft a bill along these lines, and secure its enactment into law.

RESOLVED, That the Committee be authorized to call a meeting, if they consider it advisable, and submit the drafted bill for further consideration before its introduction into the legislature.

The Executive Committee appointed Senator H. M. Dunlap, with the assistance of Sec. Grindley, to draft the proposed bill upon lines indicated by the conference that all interested take an active interest in the subject. The committee would also like to have suggested any facts or measures which should be given consideration in framing a bill directed to the end in view.

Bees Breeding in the Cellar. Dr. A. E. Mason has this paragraph in a letter we received from him dated Jan. 21:

"The statement of some of our great lights, that bees don't breed in the cellar, is given a whack every winter by my bees. I believe every colony is stronger now than when put into the cellar last November, and not a sign of disease."

EDITOR E. R. ROOT is the subject of a curious mistake that is going the rounds of the foreign bee-journals, to the effect that "Mr. E. Root, editor of American Gleanings," has for more than 50 years practiced clipping queens, and likes the practice. As Mr. Root has not yet seen 57 years, he may be excused for having some doubt as to the correctness of the statement.

DAIRY AND CREAMERY is the name of a new 16-page semi-monthly paper, devoted to the advancement of the dairy, creamery and stock interests. A free sample copy may be had by writing to J. Lewis Draper, 279 Dearborn St., Chicago, Ill., and mentioning the Bee Journal. The subscription price of the Dairy and Creamery is 50 cents a year. We will order it for you for one year as a premium if you will send us one new subscriber to the American Bee Journal, with \$1.00.

MR. C. THEILMANN, of Wabasha Co., Minn., wrote us as follows Jan. 23

DEAR EDITOR YORK: I herewith hand you \$1.00 to go in with those winners of the Dot contest who are willing to give their prizes toward the Langstroth Monument Fund. I hope that every one of the winners will consent to your ingenious suggestion, to raise and increase this fund for putting up a respectable stone over the resting-place of Father Langstroth, which he so justly deserved.

I have never read anything in all the bee and other papers that pleased me so highly as did your suggestion to the winners in that Dot contest, as it amounts to a big sum if all consent, while none will feel any poorer in giving the small amount, and all will feel cheerful to think that they

are having an interest in honoring Father Langstroth with a monument.

Yours truly,

C. THEILMANN.

Yes, Mr. Theilmann, you would be surprised to see how many have thanked us for suggesting that the Dot cash prizes be turned into the Langstroth Monument Fund. Of course none of them will feel a contribution made in that way. Many only regret that their amounts are not larger. But to all from whom we do not hear by Feb. 15, we will mail the amounts due them; and all who notify us to place their prize amounts in the Monument Fund will be acknowledged in the Bee Journal later on, no matter if it is only a nickel contribution.

MR. H. W. BRICE, a prominent bee-keeper and writer in England, says in the British Bee Journal that the fruit crop on a farm near one of his out-apiaries is worth \$500 a year more than it was without the bees. So says an item in Gleanings. It is just such intelligent and conclusive information as this that will help to cure the blindness on the part of many fruit-growers who are enemies of bees when they should be their friends.

MR. H. W. BUCKBEE'S Seed and Plant Guide for 1899 is one of the most elaborate and complete catalogs we have seen this year. It contains 132 pages, and will be sent to you free upon receipt of your name and address. Write for it to H. W. Buckbee, Rockford, Ill., not failing to mention the American Bee Journal when doing so. The name "Buckbee" should commend him to bee-keepers—on account of the very familiar latter part of it.

MR. J. H. MARTIN (Rambler), of Los Angeles Co., Calif., wrote us Jan. 20:

"We have had a good rain, but it is far from enough to ensure a honey crop. The conditions are however favorable to the continuation of additional rains. The absence of moisture another season would about use up the industry in this State. Still, the person that has the grit to hold on would reap a benefit in the end."

MR. S. T. PETTIT, of Ontario, Canada, writing us Jan. 21, said:

"I am now in my 70th year. How rapidly life glides away. You cannot realize it yet, but the serious fact will rush upon your mind before long. It is a good thing to work while we can."

Yes, we already realize how fleeting time is. It will soon be 15 years since we first began to work on this journal, and yet it seems only a few months ago. Being so busy helps to speed time on its way. Verily, "It is a good thing to work while we can," for "the night cometh when no man can work."

DR. F. L. PERRO, of Chicago office in Central Music Hall, is well known to many of our readers, as he has written quite frequently for our columns, and also has attended several national conventions. He visited the Pacific Coast some time ago, and called on some of the bee-keepers. Here's what he has to say about his meeting Prof. A. J. Cook, who lives near Los Angeles, Calif.:

"What! Didn't I tell you about meeting Prof. Cook in Santa Barbara, on my recent visit to California? Well, I did, and I envied his delightful situation. Seated like a king on his (street-car) throne, surrounded by as charming a bevy of ladies as you could see in a great journey, there he was, dispensing smiles and information as easily and genially as if it were an every day occurrence. Oh, did you say? Bless you, no! He's not that kind. He'll be young another 50 years, at least."

The very next day I met him again. This time I cornered him! I sat in his seat, next to the aisle, and he had to stay in that railroad car. Couldn't get out. Then we had it. He told me much about his part of the State, near the famous Redlands' about bees, and the new house he was building, etc.; and told in so delightful a way I was charmed with his engaging companionship. I wanted to ask a lot of other questions, but you know how quickly time passes in pleasant company. Almost before I knew it we were toot-tooting into Los Angeles, and there our paths diverged.

"Joy be to him and his, always." DR. PERRO.

Logwood is reported, in Southland Queen, as the best honey-plant in the island of Jamaica. It comes into bloom in January.

Cypress Half-Barrels for Honey are preferred by Dr. Blanton. When dry they weigh 27 to 29 pounds, and absorb three pounds of honey. Gleanings.

Drone-Cells Opposite Worker on Same Comb. "I once had a full sheet of heavy brood-foundation, one side every cell drone-comb, whilst the other was all worker," says J. W. Green, in Australian Bee-Bulletin. Is there no possible chance for mistake in that?

To Stop Robbing. Set in a new place the hive that is being robbed, and put in its place one of the strongest colonies. Do this in the evening. Robbers begin work early in the morning, and will get a warm reception. After a little fighting they will give it up.—Gleanings.

A Woodpecker's Work. A bee-keeper was greatly surprised to find that a colony that had been unusually heavy had become very light. A hole was in the side of the hive, and on watching he found a woodpecker was the aggressor, perhaps being aided by others. Wegweiser.

Market Quotations appear to glory in giving the lowest prices, says the Canadian Bee Journal, and if in Toronto, Montreal, or some other cities a few culls have been sold at 6½ cents a pound, the public, without explanations, see in the press that comb honey is selling at from 6½ cents to . . . The tendency of this is to depress prices.

Darkening Hive-Entrances for Winter. Franz Ebster, in Deutsche Imker, considers it of very great importance that colonies wintered out-doors should have the entrances well shaded. During the winter rest the bees should not be able to tell day from night, least of all should they be able to tell that the sun is shining. They will keep quieter, consume less, and endure the winter better.

Arizona Honey. C. A. Hatch says the principal sources in the Salt River Valley are three: mesquite, which does not yield every year, and gives honey a shade darker than good white clover; alfalfa, the main reliance, with honey nearly equal to that of Colorado or Central California in flavor, but much darker; ground-cherry, which yields some years largely, and compares favorably with eastern buck-wheat.—American Bee-Keeper.

To Prevent Swarming. R. C. Aikin says there are two ways: "Hive the queen and bees in one section of the hive just as the flow comes on, making a new or strengthening weak ones with the brood, or by excluding the queen from part of the hive 10 days prior to the flow; then at the beginning of the flow take the queen and unsealed brood to a new stand, and give the bees and sealed brood on the old stand a ripe cell or virgin queen." Progressive Bee-Keeper.

Credit to Whom Credit is Due. This Boiler was obliged to get down on his marrow-bones because when mentioning some items brought out in the discussions of a convention, he failed to mention that the report of the convention was given in Canadian Bee Journal. Will the editor of that esteemed journal please print some words that will show he has assumed the same attitude when he notices that he has omitted to give any credit for the first half of page 452 in his paper?

Doolittle on Adulteration. Mr. Doolittle, in the Progressive Bee-Keeper, thinks there is more noise about adulteration than the facts will warrant; that there is less adulteration now than formerly. If Mr. D. will go over the markets, as some of us have done, especially in the large cities, I think he will have reason to change his mind. It is true, honey has come down in price, and so also has glu-

cose, and very nearly in proportion. If Mr. D. will take the pains to get the price on glucose by the carload he will find that there is a good margin for adulterating yet. If there were not, there would not be so much of it. I dislike to talk about adulteration as much as any one; but if we bee-keepers try to cover up the fact, or try to convince ourselves that it is not as bad as some folks think, the glucose-mixers will take new courage. All they want is to be let alone. In that respect they are like the saloon-keeper, whose business Mr. Doolittle and I mutually despise. Gleanings.

Cleaning in the Spring. In the Progressive Bee-Keeper, R. C. Aikin says to clean up hives and frames in April or May, depending on latitude and season, and the bur-combs trimmed off will pay for the labor, leaving the combs much pleasanter to handle throughout the season. Doolittle thinks not enough wax could be accumulated in one season to pay for the work if top-bars are ½ to ⅞ thick, as used now by most apiarists. When he finds a colony gives an extra amount of bur-combs, he replaces the queen.

Getting Frames Filled with Brood. Frames which have brood at the front end and honey at the back are reversed by R. C. Aikin, in the early season, or if the hive allows, it is turned half around, so the brood will be at the rear and the honey toward the entrance. This makes the bees fill up the whole of the frame with brood. A good scheme, where honey is thus found in one end of frames, but those whose bees fill the frames with brood from one end to the other without any attention on the part of the bee-keeper, are saved the labor of such manipulation.—Progressive Bee-Keeper.

The Dickel Theory has taken up a good deal of space in the German bee-papers, but has been little noticed on this side the water. The theory is that all the eggs laid by a fecundated queen, whether in large or small cells, are fertilized alike, and after they are laid the workers decide their sex by the food. L. Stachelhausen, himself an able bee-keeper and a well-informed German, gives, in the Southland Queen, an account of the theory, then gives some arguments of his own and others to show the fallacy of the theory, saying, "It is astonishing that this controversy could have so much space in German bee-papers, and that a man like Mr. Dickel could have any influence."

Making One's Own Hives. W. Z. Hutchinson says he buys sections and shipping-cases, but makes his hives. He is "near planing-mills that have good machinery and competent workmen," with lumber cheap, so it costs him much less than to send to a bee-hive factory. But that's hardly making his own hives. I suppose the only difference between him and me is that he gives special instruction how his stuff shall be cut. He says wisely that each one must decide for himself which is best for him. [W. Z. Hutchinson does just the right thing; but there are few, comparatively, who are so favorably situated. By far the great majority are out of the vicinity of cheap lumber. Indeed, they could buy the hives all made up in the flat about as cheaply as they could buy the same superficial surface of plain lumber. Ed.] Gleanings.

Larvæ in Queen-Cells. R. C. Aikin, in Gleanings, says he has unqueened about 1,000 colonies in the past nine years. He always counted that there would be positively no swarming for 10 days after the unqueening. He aimed to visit the unqueened colonies the ninth day after unqueening, when no unsealed larvæ would be present, but frequently it happened that queen-cells were not cut till the 10th and 11th days, and sometimes not till the 12th and 13th. He found that a very small percent would have a queen emerge the 10th day after the unqueening, and even a very small percent the 11th day, while some went to the 13th and 14th days. Probably half the colonies had a queen to emerge by the end of the 12th day, tapering from that to the 15th. Counting 16 days to mature a queen, the majority must have started with larvæ not more than four days from the laying of the egg, and by far the larger part inside of five days. But this does not at all prove that such queens are equal to those reared for swarming or supersedure. The editor is very emphatic upon this point, and says in a footnote: "If there is any one thing about which I feel pretty sure, it is that queens reared from cells built in a colony that is suddenly made queenless, are not the equal of swarming or supersedure queens, in prolificness, size, or longevity."

Root's Column

We have a great many interesting things to show you, but owing to a want of space we can present to your consideration only one thing at a time.

Our 1899 Fences....

The Fences that we sold last year were so nearly perfect that the illustrations in our Catalog for last year answer for the 1899 goods. There is, however, a slight difference. The cross-slats, instead of being 1/2-inch wide, are 5-16, and the slats themselves a little narrower—just enough narrower so that the top slat will drop down 1/4-inch from the section, shown at A, in the drawing below.

We are almost daily receiving very flattering reports of honey put up in plain sections. Mr. J. E. Crane, of Middlebury, Vt., one who has no interest in supplies, having recently been over the markets of the East, says that honey in plain sections was all cleaned up in some markets, and that there was a demand for more. While this may not be true in other markets, it is a fact worth considering. When you place your order for comb-honey supers the coming season, consider.

But the Fences and Plain Sections are not the only latest feature to our Supers and Hives. In the next issue we will show you some conveniences that will be readily appreciated.

Keep your Eye on this Column, for it may save you Dollars.

The A. I. Root Company
MEDINA, OHIO.

In the multitude of counsellors there is safety. Prov. 11 14.

Bee-Keeping as a Business.

Query 80. Would you advise any one to follow bee-keeping as a business in the United States? That is, to depend upon its results for a livelihood, be a specialist in honey-production?—ANON.

S. T. Pettit Yes.

W. G. Larrabee No.

Prof. A. J. Cook That depends. Yes and no.

Chas. Dadant & Son Yes, provided you do not keep less than 300 to 500 colonies.

G. M. Doolittle Well, that is what I am doing, and what I do any one else can do.

Jas. A. Stone I am of the same mind in bee-keeping as in farming don't believe in specialities.

Dr. J. P. H. Brown Best not to risk all your eggs in one basket. Have some more strings to your bow.

R. L. Taylor No, not any one, but any one who has a taste for it, and who is able-bodied, active and skillful withal.

J. M. Hambaugh Location has much to do with this question. I would say yes were the conditions right; otherwise, no.

Eugene Secor There may be localities where bee-keeping as a business will pay, but such places are not plentiful, in my judgment.

O. O. Poppleton No man can fully advise another a stranger what business to follow. I have myself been doing as the question suggests for over 20 years.

Emerson T. Abbott Not unless you have a good farm to fall back on. Bee-keeping is a part of agriculture, and, as such, should be carried on with other agricultural pursuits.

J. A. Green Doubtless there are many localities where a specialist would do well. But I believe the time has past for bee-keeping as an exclusive business in my locality.

A. F. Brown No, sir! True, there are lots of specialist men who make the production of honey their sole business and livelihood. Still, it's a business equal, almost, to gambling.

C. H. Dibbern It would not do in my locality, as there are entirely too many failures in seasons. There are no doubt many sections where such a course would be safe and profitable.

Mrs. L. Harrison Not every one; special qualifications are needed not only a good producer, but a good seller. A careful, painstaking person who looks after the odds and ends may succeed.

R. C. Aikin Specialism requires more of a reserve bank account to tide over failures than does "mixt farming." A mixture may succeed almost anywhere; specialism only in favorable localities. In the right field, and

SWEET CLOVER

And Several Other Clover Seeds.

We have made arrangements so that we can furnish Seed of several of the Clovers by freight or express, at the following prices, cash with the order:

| | | | | |
|--------------------------|-----|--------|--------|--------|
| Sweet Clover | 5lb | 10lb | 25lb | 50lb |
| Alsike Clover | 60c | \$1.00 | \$2.25 | \$4.00 |
| White Clover | 70c | 1.25 | 3.00 | 5.75 |
| Alfalfa Clover | 80c | 1.40 | 3.00 | 5.00 |
| Crimson Clover | 60c | 1.00 | 2.25 | 4.00 |
| | 55c | .90 | 2.00 | 3.50 |

Prices subject to market changes. Add 25 cents to your order, for cartage, if wanted by freight. Your orders are solicited.

for the greatest success financially, I say yes; but for the most enjoyable life and the best citizenship, I say a mixture.

D. W. Heise I cannot say as to the United States, but as a Canek I would consider it unwise for any one to launch into bee-keeping as a specialist, and depend upon it for a livelihood in Canada.

Rev. M. Mahin I would advise the very few—not the many—to make the business a specialty, and to depend upon it mainly for a living. But in general it is not well to carry all the eggs in one basket.

J. E. Pond No, I would not. Not one in 50 can do so and make a success. I speak generally. Once in awhile a good living can be made, by a person especially fitted by Nature and study, but as a rule it can't be done.

P. H. Elwood Bee-keeping has afforded for the past few years a very poor living to a majority of those who depend entirely upon it. Whether prices and other conditions will permanently improve remains to be seen.

Dr. C. C. Miller That depends. Certainly not, if money is your chief aim. If the most you care for is to live a healthy, happy, and useful life, even then it will hardly do to make bee-keeping your sole business, unless you have some money laid by to fall back on.

G. W. Demaree I would not advise every one to enter the bee-business, far from it. If your inclinations lead in that direction, and you have no business that pays for your time and labor, honey-production offers a field of fascinating work with fair profits to the man suited to the business.

E. S. Lovesy Under favorable conditions, yes. I am trying to make my living in the business. Without saying whether I have acquired it or not, I would advise a practical knowledge in the bee-business, as it is more or less like Paddy's flea—now you think you have it, and now you don't. The bee-keeper is liable to a hundred accidents or misfortunes, and if he would obtain success he must be able to grapple with and apply all necessary remedies at once.

Expects Successful Wintering.

Bees are all in the cellar and apparently very contented, with every prospect of a successful wintering. The past season was a rather moderate one here, and in Cairo, this State, while my bees in Colorado have done better than for several years.

Greene Co., N. Y., Dec. 26—O. R. Vog.

Bee Journal Worth \$105 to Him.

I would not be without the Bee Journal, for it is worth its weight in gold to every bee-man who keeps bees. I can't see how a bee-man can do business in selling honey and wax if he is not posted on the market prices and crops of the different States. Last year I had over 12,000 pounds of honey. I sold my honey from 4 to 4 1/2 cents a pound. When the honey dropped to 3 1/2 cents I had over 6,000 pounds on hand, but I did not sell for that price. I saw in the Bee Journal

EVERGREENS

BEST EXTRACTED HONEY FOR SALE.

ALL IN 60-POUND TIN CANS.

ALFALFA HONEY.

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

BASSWOOD HONEY.

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms in Wisconsin. It has a stronger flavor than Alfalfa, and is greatly preferred by those who like a distinct flavor in their honey.

Prices of either Alfalfa or Basswood Honey:

A sample of either, by mail, 8 cents; samples of both, 15 cents - to pay for package and postage. By freight—one 60-pound can, 8 cents a pound; two cans, 7 1/2 cents per pound; four or more cans, 7 1/2 cents per pound. Cash must accompany each order. In ordering two or more cans you can have half of each kind of honey, if you so desire. This is all

ABSOLUTELY PURE BEES' HONEY,

The finest of their kinds produced in this country.

We would suggest that those bee-keepers who did not produce any honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere. "YORK'S HONEY ALMANAC" will be a great help in creating customers for honey. See prices on another page.

Bingham Smokers have all the new improvements. Before buying a Smoker or Knife, look up its record and pedigree.

FIFTEEN YEARS FOR A DOLLAR; ONE-DHALF CENT FOR A MONTH.

Dear Sir:—Have used the Conqueror 15 years. I was always pleased with its workings, but thinking I would need a new one this summer, I write for a circular. I do not think the 4 inch Smoke Engine too large.

Truly, W. H. EAGERTY, Cuba, Kansas.

January 27, 1897. T. F. BINGHAM, Farwell, Michigan.

SAVE \$8 ON A HARNESS!

We are the largest manufacturers of harness and carriages in the world selling to the consumer exclusively.

WE HAVE NO AGENTS, DEALERS OR MIDDLEMEN.

We sell you direct from the factory at wholesale prices and save you all a national expense. We ship anywhere for examination. We guarantee and warrant everything. This Elegant Team and Farm Harness for \$19.50. Many gentlemen who have bought it report that they have saved from 18 to 20 in buying this harness from us. For full description of this and 60 other styles of harness and 15 styles of vehicles see our new illustrated catalogue. Your name on a postal card will get it.

Elkhart Carriage and Harness Mfg. Co., W. B. PRATT, Secy. ELKHART, INDIANA.

Please mention the Bee Journal when writing Advertisers.

that in different States the honey crop was light, and not of very good quality, so I kept my honey for better prices.

A buyer's agent came along and offered me 4 cents a pound. I said, "No, the honey is worth more." He argued that there was plenty of honey all over the East. I replied, "I know better." "How do you know it?" he asked. I replied, "I read a reliable paper, which gives the production of honey and prices, and that is the American Bee Journal."

"Well," said he, "Papers don't make prices," and started off. Last week he came and paid me 5 1/2 cents a pound. I sold 6,000 pounds to him, and I made a profit of \$105 over his first offer of 4 cents. This \$105 I made by reading the American Bee Journal, otherwise I would have sold the honey to him for 4 cents a pound.

Also the Bee Journal gives good information to beginners, telling them how to handle bees. F. S. BUCHHEIM, Orange Co., Calif., Dec. 22.

Bees Have Not Done Well.

My bees have done no good for the last three years, still I do not think I can do without the "old reliable" American Bee Journal. W. H. PRICE, Park Co., Colo.

Call them "Schmidt's Hardy Bees."

The North winds are blowing and our bees are flying. We take pleasure in sending you a sample of our bees, which were pulled out by the workers Dec. 18—dead ones, of course. But it is astonishing to see bees flying while one has to use an overcoat, a fur cap and mittens, to keep warm. We have 45 colonies of these "toughs" that were flying while the Italians did not show up at all. Please name these hardy bees in the "Old Reliable."

R. H. SCHMIDT & Co., Sheboygan Co., Wis., Dec. 25.

A Question of Botany.

I would respectfully suggest that your correspondents, Messrs. Moore and Golden, brush up a little on botany. They confound sunflower, *Helianthus*, with thorn-apple, Jamestown weed, Jimson weed—*Stramonium*. While sunflower would probably make good smoker-fuel, it has no narcotic properties. On the contrary, *Stramonium* is a powerful narcotic, and its smoke might be expected to subdue the most vicious bees. R. H. LEE, Carroll Co., Ohio.

Very Poor Honey Crop.

I do not see how any bee-man can do without the American Bee Journal!

We had a very poor honey crop here this season. ERWIN GABRIEL, Green Co., Wis., Dec. 26.

Gathered But Little Surplus.

I have seven colonies of bees. I am not getting rich at them, and fuss with them for a supply for the house. This year they gathered but little surplus. L. D. THURSTON, Wyoming Co., N. Y., Dec. 27.

Honey-Dew, Sweet Clover, Etc.

I commenced the season of 1898 with 50 colonies, increased to 53, and got 700 pounds of the darkest stuff I ever saw. I sold it at 8 1/2 cents a pound—all my conscience would allow. It was gathered from the tops of large timber, white oak mostly. I would give something pretty to know what it comes from.

My bees are not in as good condition for winter as I would like, but the prospects are good for next year, for white clover honey.

Will sweet clover do any good 160 miles south of Chicago? It has bloomed for two

MONEY IN SEEDS FOR YOU!

The Greatest Opportunity to **MAKE MONEY** that may ever Come to You!

You are sure of the **Finest Garden Vegetables** and stand twelve chances to make from \$500.00 to \$5,000.00. From a single package of seed, in 1898, Mr. F. C. Jameson, of Boston, Mass., cleared \$500.00 and writes that he will clear \$5,000.00 in 1899.

SPECIAL OFFER!

With 500,000 New Customers in 1899 and will send the Liberty Collection, comprising 12 Liberal packages of the following New Seeds—Beet, Red Cross, the only Brussels Sprouts, Dwarf Perfected, Carrot, Golden Root, Celery, Broquet, the finest, Musk Melon, Triumph, the best Water Melon, Everbearing, sweet red core, Parsley, Grosseille, Pepper, China Crown, fruits often sell for 10c each, Radish, Golden Market, Squash, Early Spring, Tomato, Roseland Peas, and the Wonderful Cuban Giant Onion—Just paid for only **25c**, to cover postage and packing—together with my New Catalogue for 1899—tells how to Make the Garden and Farm Pay. Handsomely illustrated and up-to-date. You can't afford to be without it. Over ten millions of dollars made in 1898 by planting Buckbee's Seeds. years here, and the bees have workt on it very little. How does it do in Michigan, say about Oceana and Mason Counties? How is that county for bees, anyhow? I have just been down in Florida, but I could not recommend it in any way except for health, water and climate.

R. R. STOKESBERRY,
Vermillion Co., Ind., Dec. 28.

[Will any one who knows, kindly reply, briefly, to the questions askt in the foregoing?—EDITOR.]

Had a Good Season.

We had a good season with the bees this year. My best colony produced 144 one-pound sections of honey. Of course we give the American Bee Journal credit for part if not all of our success.

I have in the cellar now 33 colonies, all of which I think are in good condition for winter.

Success to the American Bee Journal.
H. W. SAVAGE,
Sauk Co., Wis., Dec. 26.

Bees' Earnings Satisfactory.

For some years I have been handling bees as an amateur. Last season my colonies had so increast that I purchast others and establish an apiary, having now between 70 and 80 colonies. The spring and early summer were too rainy for the best results; but, after all, the earnings of my workrs were satisfactory. In this new industry I have found the Bee Journal of great value. Its information is practical and useful in a high degree

E. STUART, M. D.,
Ellis Co., Tex., Dec. 29.

A Very Poor Season.

I have 55 colonies of choice-bred Italian bees wintering on the summer stands, and all seem to be in good condition yet. The past was a very poor honey season. I had only about a third of a crop, and that all buckwheat, but of the very best quality. A great many bee-keepers did not even get a third of a crop, but nothing.

PAUL WHITEHEAD,
Luzerne Co., Pa., Dec. 27.

Poor Honey-Year, Etc.

It has been a poor honey-year with us. I had 10 colonies, spring count, and have 17 packt on the summer stands for winter. Not half an average crop of honey this fall. I am over 70 of a century old, and am

Page & Lyon Mfg. Co.

NEW LONDON, WIS.,

Operates two Sawmills that cut, annually, eight million feet of lumber, thus securing the best lumber at the lowest price for the manufacture of **Bee-Keepers' Supplies**...

They have also one of the **LARGEST FACTORIES** and the latest and most improved machinery for the manufacture of **Bee-Hives, Sections, &c.**, that there is in the State. The material is cut from patterns, by machinery, and is absolutely accurate. For Sections, the **clearest and whitest Basswood** is used, and they are polishd on both sides. Nearness to Pine and Basswood forests, and possession of mills and factory equipt with best machinery, all combine to enable this firm to furnish the **BEST GOODS AT THE LOWEST PRICES.**

growing neither younger nor handsomer, but feebler. I was an editor once, for more than 30 years, on a daily paper, but quit that 10 years ago—then spent three years writing a history and now am on a farm, with inability to work it—can only do some choring, take some care of the bees and Belgian hares, and cultivate the garden a little.

ALBERT BAXTER.

Muskegon Co., Mich., Dec. 28.

Too Dry for Bees.

Bees did not do very well the past season, as it was too dry from July on. I have 16 colonies, and got only 250 pounds of honey. Last year was a little better, as I got 450 pounds.

R. H. BERGFELD.

Hardin Co., Iowa, Dec. 29.

A Poor Season in 1898.

We had a poor season here—160 pounds of comb honey from 21 colonies. One colony stored 21 pounds of surplus, while a number put none in the supers. There did not seem to be much nectar in anything. Bees are out strong today, seeming to be in good condition. I hope next season will be a good one. Success to the Bee Journal.

W. M. MILLER.

Franklin Co., Kans., Dec. 28.

Bees in Bad Condition.

Bees did very poorly here this season, and are in bad condition to winter. They have good honey, but the bees are all old.

D. S. BURBANK.

Blackhawk Co., Iowa, Dec. 25.

Bees Did About Medium.

The American Bee Journal is a fine bargain at \$1.00, and should be snapt up by every bee-keeper in the land.

Bees did about medium here last season. From 14 colonies I got 1,024 pounds of honey, one-third comb, and increase to 20 colonies.

L. DICKERSON.

Grayson Co., Tex., Dec. 28.

Bees Wintering Finely.

I can't keep bees without the American Bee Journal. My bees are all in the cellar and doing finely.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Jan. 9.—The trade is not active in comb honey, many of the retail dealers being supplied with sufficient stock to meet demands for some time to come. Prices are quite steady with 13c for best white, off in color, etc., including amber grades, 10⁰⁰ 12c; dark, 9c. Extracted 6⁰⁰ 7c for white; amber and dark, 5⁰⁰ 6c. Beeswax, 27.
R. A. BURNETT & Co.

DETROIT, Jan. 2.—No change in supply of honey as to quality, but prices are somewhat lower than last quotations, viz: Fancy white, 13c; No. 1, 12⁰⁰ 12⁵⁰ c; Fancy dark and amber, 9⁰⁰ 11c. Extracted, white, 6⁰⁰ 7c; dark, 5⁰⁰ 5⁵⁰ c. Beeswax, 25⁰⁰ 26c.
M. H. HUNT.

INDIANAPOLIS, Jan. 4. Fancy white comb, 12⁰⁰ 12⁵⁰ c; No. 1, 10⁰⁰ 11c. Demand fairly good. Dark comb honey is being offered at 8⁰⁰ 9c with almost no demand. Clover and bass-wood extracted, 6⁰⁰ 7c. Beeswax, 26⁰⁰ 28c.
WALTER S. POWDER.

NEW YORK, Jan. 20. Fancy white, 12c; No. 1 white, 10⁰⁰ 11c; amber, 9c; buckwheat and dark, 7c. Extracted in good demand at unchanged prices. Beeswax rather quiet 27⁰⁰ 28c.

Trade in comb honey is quiet. White is pretty well cleaned up, but there is a large stock of buckwheat, amber and mixt, having accumulated of late, and in order to sell in quantity lots it is necessary to shade quotations.

HILDRETH BROS. & SEIGELKEN.

BOSTON, Jan. 9.—Fancy white, 13⁰⁰ 14c; A No. 1, 12c; No. 1, 11c; light amber, 9⁰⁰ 10c; buckwheat, no call. Extracted, white Northern stock, 7⁰⁰ 8c; Southern stock, 6⁰⁰ 7c. Beeswax, 27c.

The demand for honey seems to have dropped out of sight during the holiday season, but now that it is over we hope to see a better call for it. There is abundance of stock on hand and it now looks as if the expected shortage would not materialize.

BLAKE, SCOTT & LEE.

KANSAS CITY, Jan. 25. Fancy white comb, 13c; No. 1, 12c; amber, 11c; dark, 10c. Extracted white, 6c; amber, 5c; dark, 4⁵⁰ c. Beeswax, 25c.
C. C. CLEMONS & Co.

BELLEVILLE, Jan. 27. There is a little more activity on strictly Fancy 1-lb. combs at 12c. The bulk of receipts of low grades sell at 10c, down to 7c, and in a few cases, even less. A moderate amount can be sold every day. Extracted, 4⁰⁰ 6c, according to quality.

BATTERSON & Co.

CLEVELAND, Jan. 2.—Fancy white, 13⁰⁰ 14c; No. 1 white, 12⁰⁰ 13c; A No. 1 amber, 10⁰⁰ 11c; No. 2 amber, 9⁰⁰ 10c; buckwheat, 8c. Extracted, white, 7c; amber, 6c; buckwheat, 5c.

A. B. WILLIAMS & Co.

MILWAUKEE, Jan. 9.—Fancy 1-lb. sections, 12⁰⁰ 14c; A No. 1, 12⁰⁰ 12⁵⁰ c; No. 1, 11⁰⁰ 12c; dark or amber, 8⁰⁰ 11c. Extracted, in barrels, kegs and pails, 6⁰⁰ 7⁵⁰ c; dark, 5⁰⁰ 5⁵⁰ c. Beeswax, 25⁰⁰ 27c.

The condition of the market is favorable for shipments of honey, especially of best grades, which are in small supply. The sales are moderate, but we are expecting an increased demand and good trade this spring.

A. V. BISHOP & Co.

Convention Notice.

Wisconsin.—The 15th annual meeting of the Wisconsin State Bee-Keepers' Association will be held Feb. 9 and 10, 1899, in Madison. Many experienced bee-keepers will be there. The following is a part of the program:

- "What to do with Unfinished Sections"—John Trimberger, of Clark Co.
- "Working an Apiary for Comb Honey without Increase"—H. Lathrop, of Green Co.
- "Short Cuts in Extracting Honey"—Frank Mimick, of Sauk Co.
- "Handling and Shipping Extracted Honey"—G. W. Wilson, of Vernon Co.
- "Selling Honey"—Gustav Gross, of Jefferson Co.
- "Selling Comb Foundation"—Aug. Weiss, of Outagamie Co.
- "Advantage of Honey Exhibits"—Ed Ochsen, of Sauk Co.
- "Cellar Wintering"—A. G. Wilson, of Vernon Co.
- "Benefits in Attending Convention"—J. Hoffman, of Green Co.
- "State Foul Brood Report"—N. E. France, of Grant Co.
- "Future Prospects of Wisconsin Bee-Keeping"—F. Wilcox, of Juneau Co.

As many other State Societies will be in session the same week in Madison, there will be excursion rates to all who take receipts of their railroad tickets.
F. Wilcox, Pres.
N. E. FRANCE, Sec., Platteville, Wis.

The...Afterthought.

The "Old Reliable" seen through New and Unreliable Glasses.
By "COGITATOR."

INTRODUCTION.

LINE upon line, precept upon precept," is the way to instruct. The effect of bee-medicine is much of it lost for want of somebody to come afterward and rub it in through the cuticle—and therefore here comes your humble servant to put you in mind of what you read several weeks ago. It's a peculiar job, tho, because different sorts of patients require different kinds of rubbing. The rubbing that would do nicely for chilblains or callousities might cause the gouty patient to knock you down with his crutch. And, then, the medicine suitable for colic might not be just the thing for insomnia; and in doctoring through the printing press we have to deal out the medicine to all, like an army ration. (All this will make you think it's Dr. Peiro that's starting in again; but of course shrewd judges will perceive that "Cogitator" is only another alias for the editor.)

THE PORTRAIT OF DOOLITTLE.

The first thing that strikes us in the new year is how different the portrait of Doolittle looks from all his previous pictures. Looks as if he had just been doing something naughty, and was inwardly chuckling about it. Cogitator thinks the multiplication of bee-men's pictures is getting to be a nuisance, very like the pictures of folks cured of something by somebody's dollar-a-bottle stuff. But this does not hit Doolittle at all. It is a high honor to be the foremost practical bee-man of the whole world; and we are more than willing to contemplate a new picture of our leader any time. The point suggested is this: Pictures of nobodies continually thrust before us obliterate from the mental retina the pictures of the somebodies which we would like to retain.

EVERYBODY HIS OWN QUEEN-REARER.

Doolittle's article says, "No person is an accomplisht apiarist until he is a thorough master of the queen-rearing part of the business." May be that's the truth; but it hits a lot of us unpleasantly hard—the happy-go-lucky way of letting our bees rear their own queens entirely comes so easy—easy as slumber to the sluggard. Mr. D. backs his unpleasant assertion by reminding us that when we happen to be favored with a queen of exceptionally valuable qualities we let a big prize go mainly to waste, just because it is too

much bother to rear 50 young queens from her and introduce them.

No special value in a little frame on purpose for queen-rearing, and many disadvantages. Worth something to be told that by such competent authority. Have a good frame, and use it for queen-rearing same as for everything else.

One tiptop idea that needs rubbing in is, that nuclei with queens always build worker-comb; and combs with holes in them should be given to such for them to mend up. Strong colonies mend holes with drone-comb too often. When your "hole-y" combs give out, cut out your patches of drone-comb, and have it replaced by comb of worker size. The use of a little frame for nuclei blocks this excellent policy.

It also looks as if he was right in the rather extreme advice to use a full-sized hive for nuclei—no handy way yet devised to keep little hives from being robbed which is at all comparable to making the bees enter one side of a big hive, and then go across it to their compartment on the other side. Unless the nucleus is unreasonably weak, robbers will almost never overcome it if so arranged. Probably robbers soon come to distinguish diminutive hives from big ones, and assume that the former can of course be beaten if the attack is sharp enough, when they would let a big hive alone in the same circumstances; just as banditti attack a cabin, but keep clear of a fort. Beginners (and perhaps most of us) need a heroic dose of capscium to wake us up to the magnitude of the robbing evils which a little forethought could prevent just as well as not.

ABOUT THOSE "AIKING" EXPERIMENTERS.

Well, how about Mr. Aikin's plan to get 20 apiarists to experiment simultaneously on problems of importance? Good; only I don't believe he half realizes the difficulty of arranging the details of the business. It is driving 20 horses in a team with a compound evener. Now and then one might fly back. And a trifle of kicking is possible, even.

Again some will say: "I am doing a full share of the work of this, and somebody else is getting all the credit of it." And at last the results would not agree; and the unsolved problems would mostly remain unsolved. When the symposium method of question-box answers was first invented we were to have all unsettled things settled right away. How many were really settled? The problems mostly stay with us to the present day; and yet the plan was worth its page-room. The present plan is likely to be worth trying; but we must not expect too much of it.

Perhaps the best of the problems he suggests for such investigation is: When a colony stores 20 pounds of comb honey surplus, how much extracted surplus *would they* have stored? His present thought is, about 25. (I cheerfully second that figure.) Thinks he never once realized 40.

The question whether unqueening during harvest makes the bees less energetic in their storing, would do well for joint investigation also; but I doubt if much good would come of submitting the honey-wax ratio. Nineteen would find in accordance with previous prejudices; and the twentieth would find nothing beyond what has been found before.

Aikin says 25 pounds of surplus comb honey means 3

pounds of wax secreted. Seems to me he has got that more than twice as large as it should be. Cogitator himself thinks the current ratios should be hauled down a long way, and that a few hot shot thrown into them are seldom amiss; but let us beware of reckless overstatements. The conclusion that 25 pounds of comb honey *should* equal 90 pounds of extracted falls through if 20 pounds of comb honey contains only one pound of wax.

ON THE HIVE QUESTION, TAKE TO A TREE.

C. P. Dadant seems to think the 10-frame Langstroth hive a *small* hive. Most bee-folks began with that too-small hive; and, suspecting it sized wrongly, they jumped from the frying pan into the fire by dropping to a still smaller one. If they had started in with the 10-frame Langstroth side by side with a really big hive, they would have changed up to the big one. Well, Cogitator is not prepared to dispute that, and still less prepared to assent to it; so to climb a friendly tree seems about the proper thing to do.

PLAYING WITH THE FOUL BROOD "FIRE."

It is sad when wise and good men advise little children to play with fire. Same when so good a man as McEvoy (page 6) encourages experienced bee-folks to put healthy colonies in foul-broody hives without disinfection. As often as he does it, some of us must protest vigorously. Just as good men as he encourage the children to play with the opposite kind of fire—teach that the danger is *all* in the hive and debris, and in the bodies of the bee, and that it's nonsense to fear contagion from the honey. (Scientific experiments cited to prove it.) Between the two we should have no protection at all against our great destroyer.

VIRILITY OF DRONES FROM DRONE-LAYING QUEENS OR LAYING WORKERS.

That Australian example on page 10 seems to prove that drones from a drone-laying queen are O. K. *if*; if only there were not *unknown* Italians living in freedom somewhere near. Cogitator also thinks that laying-worker drones are sometimes virile; but the evidence he has to offer would fall quite a bit short of complete proof.

ORIGIN OF HONEY-DEW "UP HIGHER."

Prof. Cook's leading idea, on page 17, may profitably be rubbed in a great deal (even if the patients do get mad and strike). It is the nature of the aphid to *select* the juiciest and most rapidly growing shoots and gather on these in immense numbers. These shoots on a tall tree are at the top, the whole tree from top to bottom being smeared with sweet from thence. The sophomore bee-naturalist climbs up into the tree half way, looks all around sharply, then comes down and reports that there are no sap-sucking insects on the tree, when the simple fact is that he did not climb high enough to see one. Notice the most common example—the grape aphid—and you'll see how it is at once—myriads on a few tender tips, few or none anywhere else. And these words about honey-dew, from the best scientific authority on this continent, deserve to be hung up in our minds, set in capitals, and perhaps sometimes displayed before the people:

"IT IS A SECRETION AND NOT AN EXCRETION."

That is to say, when it's good it's good, and when it's bad it's bad. The way in which it is sprayed around exposes it to admixture with various kinds of dirt; and fungi are sadly free to grow in and on it; but it is not *necessarily* vile, any more than milk is. (But the kind we had here last summer was *unnecessarily* vile).

HONEY FROM ITALIANS VS. THAT OF THE BLACKS.

Mr. Bates, on page 19, makes some headway with the question. "Why Italian bees store better honey than the blacks." Now if some one will tell us, Why black bees store better honey than the Italians—why, then we'll have a mit-ten on each hand.

FASTENING BROOD FOUNDATION BY "CANDLE-LIGHT."

Mr. Thompson's way of setting foundation is ingenious, and also effective; but I suspect Dr. Miller, with the ordinary saw-cut bar, and his beeswax candle (or half a dozen of them) would securely put in about ten to his one.

THE UNCOMBINED THE BEST TOOLS.

Is it best, Mr. Bearden, to try to combine the hive-lever with the propolis-scraper? I doubt it just a little. We want the best lever and the best scraper; and combination tools proverbially fall short of the uncombined.

BEEES FEEDING CAGED QUEENS.

Dr. Miller mostly rubs in his own medicine pretty well, and to have another doctor come around and tinker hardly sounds in accordance with the fitness of things. I'll venture, however, to rub a little more on his answer about bees feeding caged queens. I see no reason to doubt his conclusions; and it is of prime importance to remember that a normal colony will *sometimes* let them starve; and that a good, strong colony unqueened will always feed them. (Doolittle wants us all to be queen-breeders, you remember.)

WRONG ABOUT FACING HIVES.

Guess Ben Honnett is wrong when he says (page 22) that it is unimportant whether the hive faces east, west, north or south.

JOINT STOCK COMPANY A SMILE-PRODUCER.

I indulged a smile at that Colorado joint stock company, to be started on \$160, mainly paid in truck. When it comes to cash expenses in securing a market, most bee-folks seem to think that apiculture is all the same as religion.

WOULD LIKE TO SEE THAT FIBER HONEY-PAIL.

That fiber pail, on page 23, that holds cold water indefinitely, and takes eight hours of hot water to soak its joints loose—well, I should like to see it. Would think it promising were it not for the one word—reliequifying.

KIND WORDS DON'T "BRUISE" HARD.

It is really good to hear, as we do on page 25, that the subscribers are treating our editor to an avalanche of kind words beyond all precedent. Send 'em on. Avalanches of that sort don't bruise a fellow badly enough to require arnica.

"BOILER'S" BAGGED BEES.

The one thing in "Beedom Boiled Down" which I will touch this time is the plan of transporting bees in a bag separate from hive and combs. It may take a long time to get all the details of this just right; but I am strongly impressed with the feeling that an important advance will sometime be made on this line. But many stubborn muddles will have to be trepanned first, to let in the fact that honey alone is not adequate food for bees. In the hive they chew cocoons, and lick out the dried larval food and excreta hidden between; but if bagged long, some corresponding food must be given. Cogitator has tried bagging bees, and discovered that after awhile they tear the dead bodies of their comrades apart, and suck the interior.

THE EDITOR "OFF HIS (HONEY)-BASE."

Probably our editor was a little off his base in intimating that a third of a section of honey, eaten as food, with only such other viands as fitted in nicely, was an unreasonable meal. But first be sure that your stomach fully tolerates honey. Some stomachs do not. And if the honey should be aught else than best quality (color not being quality in this case) go slow on it.

SALICYLIC ACID TO "SWEETEN" SOUR HONEY.

A. W. Hart, page 29, wants salicylic acid to put in his sour honey. Tut, tut! Unhealthy stuff. Feed it to the pigs (not the acid, but the honey), and ripen up your honey before you extract it next time. COGITATOR.

York's Honey Almanac is a neat little 32-page pamphlet especially gotten up with a view to create a demand for honey among should-be consumers. Aside from the Almanac pages, the forepart of the pamphlet was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample for a stamp; 25 copies for 40 cents; 50 for 60 cents; 100 for \$1.00; 250 for \$2.25; 500 for \$4.00. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

Langstroth on the Honey-Bee, revised by the Dadants, is a standard, reliable and thoroughly complete work on bee-culture. It contains 520 pages, and is bound elegantly. Every reader of the American Bee Journal should have a copy of this book, as it answers hundreds of questions that arise about bees. We mail it for \$1.25, or club it with the Bee Journal for a year—both for only \$2.00.

Successful Bee-Keeping—Some of the Requisites

BY G. M. DOOLITTLE.

TO be successful, the bee-keeper must have a simple movable-frame hive of some kind, and for comb honey the brood-chamber should not contain more than from 1,800 to 2,000 cubic inches, inside the frames.

All know that bees gather honey instead of producing it, and that the eggs laid by the queen produce bees, consequently the more eggs the queen lays the more bees in the hive, and the more bees we have the more honey they gather. In fact, the queen is the producer of the honey. Therefore, if we wish good returns from our bees, we must see to it that we have good prolific queens, and that they fill the combs with brood before the honey season commences, so that when the honey harvest comes the bees will be obliged to place the honey in the section-boxes, as there will be nowhere else for them to store it.

But how shall we secure combs full of brood and plenty of bees to carry on the labors of the hive by the time our honey harvest begins? As soon as spring opens, our bees should be examined by lifting the frames of each hive, and if the colonies are weak, the bees are shut on one side of the hive by means of a division-board, so as to keep up the necessary heat for brood-rearing, on as few combs as they can cover. As soon as the queen has filled these with eggs, they are spread apart so as to insert an empty comb between those occupied with brood, and in a few days the queen will fill this also, and so we keep on until every available cell is occupied with brood.

Thus it will be seen that instead of the queen laying her eggs on the outside of the cluster, where it is comparatively cool and not so well suited for the youngest brood, she lays them in the center of the brood-nest, where it is the warmest of any place in the hive.

After the hive is filled with brood and bees, it does not make so much difference, as the weather is warm by this time, and bees are plenty, so that the queen can deposit her eggs anywhere in the hive to advantage. As soon as the strongest colonies are full, take a frame of brood just gnawing out, and place it in the weaker ones, giving the stronger one an empty comb for the queen to fill again, and so keep on till all are full.

When this is accomplished put on the section-boxes, and as was said before, if any honey is gathered it must be put in the boxes. Each section should have a small piece of comb attach to the top of it for a "starter," or be filled partly or fully with comb foundation of the thinnest make, to entice the bees to work more readily in them; while the center tier of sections should, if possible, be full of comb left over from the season previous. As soon as the first few sections are completed, they should be taken off before being colored by the bees traveling over them, and empty sections put in their places, thereby causing the bees to work with renewed vigor to fill the empty space left where the full sections were taken out; and thus keep taking full sections and putting in empty ones to take their places, as long as the honey season lasts.

But there is another thing which plays an important part in this matter, and that is a thorough knowledge of the location we are in. In nearly all localities where bees can be kept there are certain plants or trees which give a yield of nectar at a certain time of year, while aside from this there is little more honey obtained by the bees than is needed to supply their daily wants. Hence, it will be apparent to all that if such a flow of nectar, or honey-yield, passes by without any surplus, none can be obtained during the season. From this it will be seen that in order to be a successful bee-keeper a person must have a knowledge of the locality he is in, as well as to know how to secure the bees to meet that locality, if they are to succeed in the pursuit of bee-keeping.

Failing in this point there is no profit in apiculture. Here in central New York our honey crop comes mainly from basswood, which blooms from July 5 to July 15, and lasts from eight days to three weeks, according to the weather. In other localities in this State, white clover gives the main crop, coming in bloom June 15 to June 20, and

again in others, buckwheat, yielding honey in August; but as nearly all have a yield of honey from basswood, let us speak of that as the harvest. Bear in mind, however, that it devolves on each bee-keeper to ascertain by careful watching just when and what is the source of his surplus honey crop, so as to work accordingly. After having determined just when we may expect our harvest of honey, then the thing to do is to secure the maximum amount of bees just in the right time for that harvest, doing it as has been given above.

If a farmer has a field of grain to cut he hires the laborers when the grain is ripe, not before or afterward, yet in keeping bees few give any attention to this matter, so that, as a rule, the bees are generally produced so as to become consumers rather than producers, and thus we often hear would-be bee-keepers complaining that bee-keeping does not pay.

To know how to bring the bees and the locality together, it should be understood that after the egg is laid by the queen, it takes three days for it to hatch into a larva. This larva is fed six days, during which time it has grown so as to fill the cell, when it is capt over and remains hid from view for 12 more days, when it emerges a perfect bee, making a period of 21 days from the egg to the perfect bee. This bee now works inside the hive for 16 days more, when it is ready to go outside of the hive as a field-laborer, and at 45 days from the time it emerged from the cell it dies of old age, and another generation takes its place. From the above it will be seen that the egg must be laid at least 37 days before the honey harvest, in order that our bee has an opportunity of laboring in that harvest to the best advantage.

Now, if the harvest is basswood, commencing to bloom say July 10, the egg for our laborer must be laid on or before June 3. In this way we can calculate on any bloom, so as to have our bees ready in time for any harvest.

Allow me to say that these two factors—securing the bees, and a knowledge of our location—have more to do with successful bee-keeping than all else connected with the pursuit.

Securing a Foul Brood Law in Illinois.

BY C. P. DADANT.

I WISH to call the attention of the Illinois readers of the American Bee Journal to the short report of Secretary Jas. A. Stone, on page 765 (1898), concerning the decision of the Illinois State Bee-Keepers' Association to make an effort to obtain a foul brood law in this State, such as is now in force in Canada, and such as has lately been past in Wisconsin, where Mr. N. E. France is foul brood inspector.

Whether such laws are necessary needs but little thought. The expense to the State of an inspector such as is provided for by the Wisconsin law is insignificant if the disease does not exist in general throughout the country. Foul brood, altho of rare occurrence, is one of the most malignant diseases that prey upon domesticated animals. This disease, known scientifically as "bacillus alvei," is a fungus which attacks the larvae of the honey-bee, and causes them to die and decay in the cell with the most putrid and disgusting smell. It is contagious, and for this reason the existence of apiaries in the neighborhood of diseased colonies is threatened during the entire season, for it suffices for a bee to visit the inside of a hive which has been destroyed by this disease, to bring it home to its own colony. The larvae dying before maturity, there is no reproduction of adult insects, and the colony is doomed. The combs, the honey, the queen, the bees may, even the very walls of the hive are contaminated by the disease and made channels of infection.

There is one remedy, salicylic acid, which is successful where properly and thoroughly applied, but in most cases the safest and most rapid means of prevention of the spread of the disease is fire.

Past experience shows that when the disease once takes root in any part of the country it is likely to remain in a latent state, owing to the carelessness of some bee-owners who pay little attention to their bees. The late Chas. F. Muth, of Cincinnati, for years was compelled to fight this disease in his own apiary, owing to the neglect of neighboring apiaries. Just now the disease exists in very few parts of the country, and this is certainly the time when we can, with the very lowest cost, prevent its spreading, and destroy it from the face of the earth. Therefore such a law is timely.

But laws of this kind cannot be past by the isolated influence of a few individuals. It requires comined action. We therefore urge all Illinois bee-keepers who have an interest in the pursuit, and who appreciate what a scourge it would be, should this dread disease make its appearance in their vicinity, to write to the representative or senator of their district, and ask the extension of their vote to the bill which is about to be introduced.

I understand that Mr. J. O. Smith, the genial president of the State association, has been recommended for the State inspector. He is certainly well fitted for such work, which, I believe, will require but very little of his time at present. Better have such an appointment now than wait until the disease has made ravages among our apiaries.

I must say that, personally, I have never seen a case of foul brood, but it seems to me that I would become entirely disgusted with the pursuit if it ever struck our bees. That it is difficult to eradicate, when once established, is clear, and has been proven by all who have suffered in the past.

Friends of Illinois, do not let this subject drop out of your mind before you have done your share towards getting our law-makers to help us in this matter.

Hancock Co., Ill.

Pickled Brood: Its Origin and Prevention—Cellaring Bees.

BY DR. C. C. MILLER.

SOME time ago Miss Fannie C. Damon, of Massachusetts, wrote me about her bees, which were badly diseased. I referred her to Dr. Wm. R. Howard, to whom she sent samples of the dead bees, and he decided it was a case of pickled brood. Some points obtained from him are of general interest.

The disease is in the old pollen. If you want to keep clear of the disease, don't use moldy combs or old pollen. A 10 percent water solution of salicylate of soda will destroy the spores of the mold if it comes in contact with them, but if any bee-bread be present, the application will be useless so far as the bee-bread is concerned. When fresh honey and pollen are coming in, the disease usually subsides. Freezing will not affect the fungi.

Dr. Howard's observation is that old bees as well as young consume pollen at all times, more or less of it being consumed in winter. In all the years that he has been dissecting bees, he has never found an adult bee without pollen in the alimentary canal. Queens are also consumers of pollen.

The disease appears to be epidemic some seasons; the seasons and resulting conditions having much to do with its spread. Inferior food may have much to do with it, especially if pollen is rained on every day. If fresh pollen is lacking, sterilized (baked) rye-meal or flour may be fed.

The disease will not be conveyed to the brood unless fed in the pollen or water. It must be fed to it. Old as well as young bees must have pollen to be furnish their normal food, and the absence of it changes materially the quality of the food.

Miss Damon is somewhat puzzled to reconcile matters, as she says she has not a comb in the apiary in which mold was visible to the naked eye, and while her apiary is almost ruined, one within a mile of her and another within two miles are entirely healthy, altho she thinks they must have gathered some of the same pollen.

IS IT BAD TO CELLAR BEES WITHOUT A FLIGHT AFTER MOVING?

DR. MILLER. If I understand you correctly, you teach that it is very important to allow bees to have a flight after hauling, before putting them into the cellar. On page 16, C. Davenport tells about 20 colonies that were hauled from an out-ward and put into the cellar apparently without a flight in the middle of the winter, all but one wintering well. I think others have also said it was not necessary that bees should have a flight after they have been hauled before being put in the cellar. Which is right?

NORTH KENEG.

Perhaps neither. A rather costly experience has made me hold strongly to the view that a flight is important. One winter part of the bees in one of my out-apiaries were brought home late and did not have a flight before going into the cellar. The loss in this lot was very heavy, while the other bees in the same cellar wintered well. I know of no reason why the mortality was greater among those cellared without a flight except that one item, as in all other respects conditions were the same so far as I know. So I

feel pretty safe in saying that in that case cellaring bees without a flight after moving was a bad thing.

But Mr. Davenport says he moved bees and put them into the cellar without a flight, and they wintered well. Others have said the same thing. Evidently cellaring moved bees without a flight is not in all cases so bad a thing as I have believed. The question is whether it just happened that my case was different, or was there some difference in conditions to account for the different result? I am inclined to take the latter view. My bees were hauled when it was not very cold weather, altho too cold for them to fly, and they were probably as much frightened and excited by the journey as if the weather had been a good deal warmer.

I think those who report good success in wintering bees that were cellared without a flight after being hauled, in each case moved their bees in very cold weather (evidently Mr. Davenport did), and at that time it may be that the bees would not become so much excited as in a warmer time. Possibly they may also have been moved very quietly in a sleigh, while mine were hauled over hard roads (not very rough) in a wagon.

It is quite possible I have been wrong in thinking it did so much harm to put bees directly into the cellar after being moved in the middle of winter. But it would take considerable money to hire me deliberately to put my bees into the cellar without a flight after being hauled in the fall.

McHenry Co., Ill.

CONVENTION PROCEEDINGS

Proceedings of the Colorado State Bee-Keepers' Convention.

(CONTRIBUTED BY THE SECRETARY.)

[Continued from page 70.]

WHEN TO REQUEEN BEES.

QUESTION—What time is the best to requeen a colony?

H. Rauchfuss—We need to know what object is to be accomplished by requeening.

L. H. Northrup—I asked the question. I wish to change the character of my bees, and get a better grade.

H. Rauchfuss—Do not requeen until you can get good queens cheap. Then if increase is not wanted, introduce young queens just before swarming-time. By so doing you accomplish two objects. I did this with 40 colonies, and not one swarmed.

Mr. Martin—The most convenient time is during the swarming season, because the bees accept strange queens better then. If you have a large number to requeen, I would not buy, but get a choice queen and requeen during swarming-time.

Mr. Foster—For 15 or 20 colonies, I would requeen from the best colony as early in the swarming season as possible. For only two or three colonies I would buy queens.

Mr. Gill—Whenever a colony is poor, I would requeen any time, tho I would not interrupt them in the spring. But I would especially do so in the swarming season, choosing the prime cells for that purpose.

S. M. Carlzen—I had a queen that laid drone-eggs in the spring. If I had bought another queen early, I could have obtained three supers from that colony. By letting it go I got only one super.

USUAL AMOUNT OF HONEY TO A COLONY.

QUESTION—What is the usual amount of honey to a colony?

F. Rauchfuss—Probably the usual amount of surplus is meant.

Mr. Gill—In Wisconsin, my average for a term of 18 years was 110 pounds of extracted honey, including two years of failure. On the Western Slope, my average in comb honey has been 40 pounds; one year it was 90 pounds. This year, the grasshoppers cleaned everything out, and my bees lackt 10 pounds of anything. From one apiary of 240 colonies outside I obtained 400 cases. Perhaps the general average of the Western Slope is 50 pounds. What has it been over the State?

Mr. Adams—My average has been very little, ranging from 10 to 134 pounds—the total average being 40 or 50 pounds.

F. Rauchfuss—12½ pounds was the average surplus of Colorado last year, and it was an average season. Only practical bee-keepers will obtain the results mentioned by those who have answered the question. Many colonies kept by farmers and others do not yield anything, which reduces the general average.

H. Rauchfuss—Last fall I was requested to take off the surplus from a yard of 36 colonies. I obtained a total of three unfinished sections.

F. Rauchfuss—The yield is largely due to management. The highest average reported last year was 118 pounds. Some colonies in that man's neighborhood yielded nothing; many not a quarter as much.

Mr. Rhodes—I know the man. A number of apiaries in that neighborhood did not produce a pound. The average per colony must be very low.

BEST WAY TO STOP ROBBING.

QUESTION—What do you consider the best way to stop robbing?

A lengthy discussion ensued. The method of contracting the entrance, closing with a bunch of grass, and sprinkling with water at intervals of one or two hours was advised; also, that of trapping the robbers by an inverted shipping-case on top, and letting them go at night. These methods were criticised as being suited to well-dispositioned bees, but not generally successful. The advice was also given to drive out all the bees with smoke, and close the hive up, as a colony that is robbed is not worth much, being weak or queenless. To this it was replied that it was not good policy to close up a hive that is being robbed, as in two or three minutes the robbers will attack neighboring hives, and that it was better to leave a small quantity of honey and let them clean it out. This was in turn criticised as being dangerous advice to give to the shiftless bee-keeper near Boulder, and not good for the small bee-keeper, as it educates bees to rob. The best method is to remove the cause. Weak or queenless colonies, or those having combs broken down, are the ones usually robbed by the thrifty colonies. A lot of extracting-supers exposed will cause robbing, and sometimes supers above bee-escapes. It is contagious, and very hard to stop after getting fairly started. In small cases, when the bees are not on a regular rampage, a change of position, or a wet blanket, will do good.

EVENING SESSION.

Miss Mary C. Porter read a paper entitled,

Extracting Honey.

It is not my intention to give any prescribed rules for honey-extracting, for every bee-keeper has his individual way. The underlying principle is that by centrifugal force the honey is thrown out of the comb.

Extracted honey seems to me to be a more useful and attractive as well as more concentrated form of honey, from the absence of wax. For this reason it may be put to many uses unsuitable to comb honey.

The machine used, called an extractor, consists of a cylinder in which a wire basket is hung, of such a shape that the extracting-combs may be easily rested therein. The first extractor we used had room for but two frames, and these were lifted out and turned; but for two seasons we have used a "Cowan Improved," which holds four frames, and these turn automatically, saving much time, tho requiring more strength to propel it.

Perhaps the best way to tell you how we extract is to describe a day in the honey-field. To do a day's work one must rise early and be in the field on a sunny day by 9 o'clock. The first thing for us, as our yards are all some distance from home, is to load. We carry extractor, capping-box, knives, tools of other kinds, a small oil-stove, smokers, and our lunches, for we have a whole day's work before us, and the out-door work produces a wonderful appetite.

Our force consists of four persons, two to take the honey from the hives and carry in, two in the shop to uncap and extract. Arriving at the field of action the smokers and stove are lighted, water to heat the knives is heated (by the way, this water is excellent to make honey-vinegar), the extractor and capping-box are set up, and then we are ready.

When the honey is well capt over, two experienced persons are required to uncap, and even then the extractor is

not run to its fullest capacity. Now the capping-box: Ours is a water-tight box in which are suspended two deep sieves. These are hung within three inches of the bottom, and on a good day, at noon, about 30 pounds of good, clear honey are drawn off. The comb rests across the box lengthwise of the sieve, and we find it a great improvement over the can with a board across it, which we formerly used; the cappings drain so well, and so much honey is saved which would otherwise be greatly darkened by the solar extractor.

The honey having been uncapt, the frames are carefully scraped, which we find a great advantage in using the Cowan extractor, as otherwise the bur-combs, propolis, etc., make the baskets gummy, and greatly hinder the work. Then in storing is it not much better to put away clean, well-scraped combs and frames than those covered with a season's wax, propolis and bur-combs?

The next step is extracting proper, which, if the honey is at the proper temperature, is very easily accomplished. The person who extracts soon learns from experience about how much turning each set of combs requires, how to balance the combs to prevent undue jarring of the machine, and subsequent loss of combs, and how fast to run the machine to make all the honey fly out.

When the honey comes from the extractor, it contains particles of wax and candied honey, which must be removed. To accomplish this we have found a wire strainer very useful. The wire is about 32 mesh, and the honey passes through very easily, leaving candied honey, wax and bits of comb behind.

One thing that should be remembered by every bee-keeper, is that the honey-house should be kept neat and clean, and handy—that is, have all things in order, with a place for everything, and everything in its place.

Another year may we all be successful, and succeed in producing a good crop of the finest honey.

MARY C. PORTER.

Mr. Pease—Don't small bits of wax go through the strainer?

Miss Porter—We do not find it so.

F. Rauchfuss—Don't you re-strain when liquefying?

Miss Porter—Yes, and then we use a much finer strainer, an 80 mesh.

Mr. Porter—Couldn't the Cowan extractor be improved?

F. Rauchfuss—I saw a ball-bearing Cowan at the Omaha Exposition. A brake would be an improvement.

Mr. Martin—The Cowan is not geared high enough.

F. Rauchfuss—I reported to the Root Co. a year ago about that. I did not examine the gearing of the extractor at Omaha. I have had experience with low gearing with an extractor three feet in diameter. It would not throw out satisfactorily.

Pres. Aikin—How many have had experience in extracting in November?

Mr. Pease—I have, and I don't want any more of it.

Mr. Porter—Three years ago I extracted sections in November by using artificial heat.

Pres. Aikin—I have been planning to have enough extra extracting-supers to hold the entire crop, so that I can store it all in a building in the comb. I would go to the out-apiaries in the morning and come home with a load of honey. It is not hard to smoke bees out if there is a chamber beneath for them to run into. I would have a room equipt for heating on the second floor, closed and tight, the heat being generated in the basement. I have found that for late extracting the temperature must be high, and kept there 24 or 36 hours, and the last three or four hours it should be close to 100 degrees. I would take one case out of the room at a time and extract it, letting the honey run into a tank in the room below. The worst difficulty is with honey candying; but the plan does save lots of labor in the busy season. I cannot make a definite report of the plan. It is largely yet in the experimental stage. The basement might be built so a team and load of honey could drive right in, and a few extracting-supers at a time loaded on a simple elevator, and pulled above.

Mr. Porter—In using escapes, I had one clogged by one bee, and all the bees in that extracting-super were dead.

Pres. Aikin—I wouldn't trust the Porter escape. I would have a little room at each apiary, with a wire-screen window-escape, where the supers would be carried in from the hives and allowed to remain a short time before loading on the wagon. Two persons can take off a ton of honey in a few minutes. I would do no shaking of combs. Sometimes the outside bees will find their way in through a screen escape. In that case I would extend it up a considerable distance, or use a double one.

Mr. Porter I had a screen escape outside, which was entered and clogged up by robbers.

Pres. Aikin I would not use a cone, but two sheets, with an opening clear across the window. That plan keeps outside bees from going in, and inside bees from passing honey out. When the opening is extended, the bees will not cluster. Where they cluster robbers cluster also, and find their way in.

THE RIETSCHÉ FOUNDATION PRESS.

I have here a machine for making foundation by means of melted wax. Having had an argument with the editor of *Gleanings* on whether this machine was practical or not, he offered to pay the transportation charges if I would pay the actual cost. I did so, paying \$5.50. As near as I can make out, the transportation from Germany to New York was \$5.50, the duty \$3.50, and the expressage from New York to Denver \$2.50; or a total of \$17, if a bee-keeper there would buy one out and out. Consequently, it could only benefit bee-keepers in general by being manufactured in this country. That could be done, if they would take enough interest in it. In Europe, 14,000 of these presses are in use.

To use, the press is set on a level table, and the vessel containing the melted wax within easy reach on a stove on the right hand. A vessel containing the lubricant sets on the table behind the press. I used soap-suds. With the left hand the press is opened, and enough lubricant poured in to merely fill the press, when it is closed again. The lubricant is then poured back, opening the press slightly at the same time, so that both plates may drain thoroughly. The press being replaced in position, the left hand opens it a little over half way, while the right hand dashes in a dipper of melted wax, taking care to cover at least half of the surface on the side away from the operator. The press is then instantly closed. No particular pressure is necessary, as the wax at once solidifies. The forefingers then slightly raise the ball-and-socket attachments of the upper plate, while the thumbs press down on the lower one. The upper plate is then grasped by the wooden bar attached to it in the middle, lifted off, inverted, and the sheet trimmed while still on the plate. (If rightly done, the sheet remains attached to the upper plate when this is lifted off.) The plate is then held over where the pile of foundation is wanted, and again turned over, when it either peels off itself, or comes off with a very little assistance.

I made about 200 sheets last summer, and calculated the weight and area of 179. I figured that the foundation ran almost five square feet to the pound. When the work was progressing smoothly, I made a sheet every minute and a half without hurrying. But I did not become at all skilled in the use of the machine, and no doubt an expert could work it much faster.

To show what other English-speaking bee-keepers think of it, I will read some extracts from the *Australian Bee-Bulletin*. The question was asked, "Can any bee-keepers give their experience with the foundation wax-press?" "Gippslander" replies:

"Yes, we get on all right with one. If your wax sticks wash it well with strong soda water, and use plenty of honey-water. It makes the foundation rather thick, that's the only fault." "Australian Yankee" says: "Not a success in my hands." John Thacker answers: "If you refer to the Rietsche press, we have used them for three seasons, and find them invaluable. Difficult to use while new, but better afterwards. Foundation thicker. We find it better for bedding the wires." W. L. Davey replies: "Yes, I wasted about a week practicing on a Rietsche foundation press before I got into full working order. So far I have attained a speed equal to 50 pounds a day, or six pounds an hour. Sometimes the foundation comb is a trifle thick, but I prefer the press-made article, as the cells stand out *much further* and more truly than the mill-made. Get a sheet of each and compare them, and you'll be convinced."

Samples of the foundation are here on the table. The heavy foundation which Prof. Gillette refers to in his experiments was made on this press.

Mr. Elliott and Mr. F. Rauehfuss have also tested this press, and I will leave it to them to supply any points I have omitted.

F. L. THOMPSON.

Mr. Elliott The machine would be practical here if it could be obtained for \$5 to \$10. By means of it, when one has only five pounds of wax he can work it all up, and it is not necessary to strain it, either; any kind of dark wax can be used. I found no trouble in rapid work; I turned out sheets at the rate of a minute and a half apiece.

Mr. Porter What temperature should the wax be?

Mr. Elliott—Pretty warm—so as to make the press as hot as can be borne by the hand. I have had considerable experience with rolls. Comparing the work of both machines, this is the machine for the average bee-keeper. It takes lots of wax to work the rolls at all, and it must be purified, and kept at an exact temperature.

Mr. Martin—Is there any advantage in pressing the plates?

Mr. Elliott—No. Perhaps a little. But just a quick movement in pouring in the wax will thin it.

Mr. Martin—Is it not possible to have the plates come very close together, for surplus foundation?

Mr. Elliott—Not for surplus.

Mr. Pease—Couldn't sheets of dipt wax be used in that machine?

Mr. Thompson—It is not generally done, but I have read of one case. A bee-keeper in Italy employs a press about like this for dipt sheets, tho that press, too, is intended only for melted wax. He uses a bottle of ice-water for dipping, so as to get thin sheets.

Mr. Foster—Is any special style of dipper used to pour in the wax?

Mr. Thompson—No, just an ordinary dipper.

Mr. Foster—My brother, Oliver Foster, used to make plaster-of-paris presses for sale, using a sheet of thin foundation for a pattern. They did not last long, but they were cheap. He used a special dipper, so as to get the wax on the lower plate instantaneously. It was a tin tube with a row of holes along one side. When this was held over the plate, and turned around, the wax would all fall down at once.

Mr. Elliott—If plenty of wax is put on, it is all right. The excess is poured off.

Pres. Aikin—I should think if you got the temperature too high, the wax would stick. Wax just above the melting point poured on a board can be readily removed, but hot wax cannot.

Mr. Thompson—It does. The temperature must not exceed a certain point, which is when the machine does not get too hot to be comfortably handled.

F. Rauehfuss—From some points in the State the freight on wax is 2½ cents a pound to Denver. Supposing 22½ cents a pound is obtained, that makes the net return 20 cents a pound, for which less than 20 cents' worth of foundation may be bought, for the freight on the foundation is also 2½ cents, making the expense 5 cents for every pound of wax. The expense of rolls, therefore, is not the only item to be considered.

Pres. Aikin—In making foundation by rolls, one must have a large amount of wax melted, in tanks. In the dipping process, there is a great deal in getting the boards and wax at the proper temperature. It is a trade that not one man out of ten will be successful in. I use the Vandervort mill. I believe a low side-wall will give a thinner base when thinned by the bees.

Mr. Foster—Dadants' foundation is prest until it is transparent.

Pres. Aikin—We can't manufacture foundation prest as hard as theirs.

Mr. Foster—Some have said that it is prest too hard, and that Oliver Foster's home-made foundation is better.

Pres. Aikin—Perhaps the high pressure makes it too hard for the bees to manipulate. There is one point that has not been made prominent enough. The grain in a bar of iron made by rolling runs lengthwise. It is hard to break a bar of iron crosswise. Pound it, and it will break into strings. The same principles are embodied in foundation. I once put two pieces of foundation edge to edge, with the side-walls of one at right angles to the side-walls of the other, welded them together, and then by means of two clamps pulled the resulting piece in two. The piece which ran the direction that rolling would make weaker, when the pull was applied where it was, broke first. And yet the Dadants put out sheets which will not hang the long way of the grain. The Roots, too, say the side-walls should hang perpendicularly. So this is something even the Roots and Dadants haven't got hold of. Both the side-walls and the grain should hang vertically.

Mr. Porter—I have noticed a curve in the Weed foundation. When two pieces are put in one section, one curves away from the other.

F. Rauehfuss—The Weed foundation has more inclination to crack lengthwise than that made by the old process. It is more brittle, there is no doubt of it, tho the contrary is claimed. For surplus foundation, I could not see an advantage in the Weed foundation over the old process founda-

tion. I have not seen the equal of the Van Densen flat-bottom foundation yet for surplus foundation.

Pres. Aikin—I have had no trouble with foundation melting down, except when it is extremely hot.

Mr. Pease—Do you use full sheets or starters?

Pres. Aikin—Both. I start with full sheets and finish with starters. Quite a few agree with me that drone-comb looks just as well as worker-comb.

(Continued next week.)

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(Questions may be mailed to the Bee Journal, or to Dr. Miller direct.)

Using Fence-Separators with Scalopt Sections.

Can I use fence-separators with 7-to-the-foot scalopt sections in Simplicity-Langstroth supers? I want to use no-bee-way sections and fence-separators next season, but I have a stock of 7-to-the-foot scalopt sections on hand which I want to use first. If the fence is too thick or too thin the sections would not stand as they should on the section-holder bottoms.

MINNESOTA.

ANSWER.—If you get fences proper to use with plain (no-bee-way) sections, you can use them with your scalopt sections this year, only it will make the comb in your sections thicker and heavier than with plain separators, at least a quarter of an inch thicker.

Styles of Hives Most in Use.

1. Which are the principal styles of bee-hives most in use in the United States and Canada? and what are the dimensions of the respective frames?

2. Has the improved, double-wall American bee-hive any merits?

KANSAS.

ANSWERS.—1. Probably no frame is so generally used as the one 17 $\frac{3}{8}$ inches in length and 9 $\frac{1}{2}$ in depth, outside measure. Of the styles of hive in which the frame is used, none is perhaps more popular than the dovetailed.

2. It would be hard to find a hive without merit in any direction, but I have no acquaintance with the particular hive you mention.

The Miller Feeder Mammoth Red Clover Preserving Extracting-Combs from the Moth.

1. Please describe as nearly as you can how the Miller bee-feeder is made.

2. Is the mammoth red clover a good honey-plant? and will it blossom late in the fall?

3. How is the best way to preserve extracting-combs from bee-moths when not in use?

MINNESOTA.

ANSWERS.—1. You can make one of any dimensions, only so you get the principle right. I think if I had a new lot to make, I should make them in this way:

Make a box water-tight the same width as the hive, about 1 $\frac{1}{2}$ inches shorter, and about 5 inches deep. The depth, however, is not important. Cut down one end at the top, or rather make it in the first place so that it shall not come up as high as the other three sides by about $\frac{3}{8}$ of an inch. Now at this same end nail on the end at each corner a block 5 inches long (if that's the depth of your feeder,) $\frac{7}{8}$ wide and $\frac{3}{8}$ thick. Then nail on this another outside end. If your feeder is for an 8-frame hive, this end will probably be 13 $\frac{7}{8}$ x5. Now you have two walls at that end of your hive, and at the same end you need a third, inside, and $\frac{3}{8}$ -inch distant from the adjacent wall. Make that wall to come to the top, but it must not be so tight at the bottom that water will not leak through. Perhaps you'd better let it come within 1-16 of an inch of the bottom. Less would do, only there's a possibility it might swell enough to be water-tight. Make it, however, water-tight at the sides. Now you have three apartments in your feeder; the main apartment that occupies nearly all the room, adjoining it an

apartment $\frac{3}{8}$ -inch wide, and an apartment outside that is $\frac{3}{8}$ wide, only this last apartment has no bottom, and through this last apartment the bees can go up, and then down into the other small apartment into which the feed has leaked, or where it will leak after the feeder is filled. To confine the bees in their proper place, a cover of $\frac{1}{4}$ -inch stuff is dropt in to cover the two narrow apartments, stops being placed so it will go down just enough to be flush with the upper part of the feeder.

Put your feeder on the hive with the end where the bees go up a little lower than the other. Put into the feeder the dry granulated sugar, dish out a little place in the center and fill the dish place half full of water and let it stand two or three minutes; then pour in more water, so there will be about as much water as sugar. If you pour in the water at first without any precaution, some of it may run right through into the other side and have so little sweet in it that the bees will not readily take it. If you have flat covers, the hive-cover will be all right to cover your feeder. Otherwise you must make a cover that will do.

2. Excellent for bumble-bees, and I think some claim that hive-bees can do more on it than on the other red clover. It blossoms at the same time as the other.

3. At a time when moths are flying, the best place is in care of the bees, putting a hive full of combs under a colony. Indeed, a colony can take care of two or three hives full of combs. Before freezing weather comes the hives of combs can be taken away and piled up out-doors, covering up from the rain and making mouse-tight.

Transferring A Perennial Question.

I have one swarm in a box-hive. How would be the best way to get them into a movable 10-frame hive?

MISSOURI.

ANSWER.—That's one of the standard questions that you'll find answered in any good text-book on bee-keeping. I cannot too strongly urge those who have no text-book to secure one as soon as possible, and then become thoroughly familiar with it. Every now and then some one gets a book and reads it so little or so carelessly that when the need comes suddenly upon him he asks a question that he would find fully answered in his book if he had only been more familiar with it. After you've studied all there is in the books you'll still find plenty of things to ask about that will more than fill this department.

Daisy Fastener and T Tins.

1. What are the dimensions of the daisy foundation fastener?

2. How long should T tins be for a 10-frame Langstroth hive super?

3. Please explain how T tins are fastened in a super so they can be removed and cleaned?

NEW YORK.

ANSWERS.—1. Three feet long, 5 $\frac{1}{4}$ inches wide.

2. I don't know certainly, but probably 14 $\frac{1}{4}$ or 15 inches; 12 inches is the length of T tins used for 8-frame hives.

3. They are not fastened at all. They simply rest on bent staples that support them. When the super is turned upside down, its entire contents can be pushed out, sections, T tins and separators.

Hives Without Shade Sowing for Bees.

1. Can bees, kept in single-walled hives, painted white, remain during the summer at a place without any shade-trees? What is your advice?

2. I have about an acre of ground which I would like to sow for bee-pasture. What seed is the most advisable?

ILLINOIS.

ANSWERS.—Yes, they may do very well. I should want the shade more for the comfort of the bee-keeper than for that of the bees. It makes a difference whether there is a free circulation of air or not. One year I had combs melt down in a hive under trees where the sun never shone. Dense shrubbery on one side and standing corn on the other effectually prevented free circulation of the air. They would have been better off out in the glare of the sun with nothing to stop the breezes from reaching them.

2. If the chief object is honey, I should say sweet clover, especially if your stock has learned to like it.

United States Bee-Keepers' Association.

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee \$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., E. Whitcomb; Vice-Pres., C. A. Hatch; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dabant; W. Z. Hutchinson; Dr. C. C. Miller.

GEN'L MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

VOL. 39. FEBRUARY 9, 1899. NO. 6.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

The Afterthought is the heading of a new department begun in this number of the American Bee Journal, in charge of "Cogitator." It will probably appear monthly. The idea is to keep up a running comment on what has recently appeared in these columns to correct errors: to endorse or comment where deserved. Of course, everything that appears in the Bee Journal cannot be touched upon by the "afterthinker," but doubtless the principal things will be "thought after." We believe the new department will be greatly appreciated and enjoyed by all our readers—even by the one who indulges so freely in the cogitations.

To Our Foreign Subscribers. There are a few things that we would like to have our foreign subscribers remember. First, that *none* of our offers or advertisements in this journal, or any other, apply to any one outside of the United States, Canada and Mexico. This is because of the extra postage that is required to reach all other countries outside of the three mentioned. The price of the Bee Journal to foreign countries is \$1.50 a year, so when a foreigner sends us \$1.00 he will get this journal just eight months.

Again, we discontinue foreign subscriptions promptly at the expiration of the time paid for, as indicated by the month on the wrapper-label of each copy of the Bee Journal. Your subscription is paid to the *end* of the month given on the label. If it is "Dec 99" that means that your subscription is paid to the end of next December.

We hope our foreign readers will remember what we have said here, and thus save both themselves and us needless trouble.

Politico-Economical Discussions in Bee-Papers, in the estimation of Editor Hutchinson, of the Bee-Keepers' Review, are not desirable things, and yet he has found it easier to let such things get started than to stop them once they are started. One man blamed facing honey for lowering prices, another laid it to something else, another had views a little different, and so a discussion got under full headway that belonged more properly in some paper *not* devoted to bee-culture, only to be stopt after several pages had been used in a way hardly desired by the average bee-keeper: and when the discussion was stopt it was probably with less satisfaction to the disputants than if it had been nipt in the bud. All things considered, probably the best time to stop such discussions is before they get started—but it takes a wise man to foresee always to what end a beginning may lead. We know, for we've "been there," and weren't always "wise," even if our name does come under the "Y's."

Alfalfa the great fodder and honey-plant of the West—was the subject of an illustrated article in the Chicago Daily News of Dec. 30, 1898. It said that to the Spaniard belonged the credit of having introduced this plant into the New World. It came to them from the Moors, who brought it, together with their patient skill in irrigation, from Africa when they crost to Spain. The Spaniard in his turn carried the seed to South America, Mexico, and later to California, and from there its culture spread over the West. Alfalfa may be grown over at least one-fourth of the territory of the United States with profit and advantage—nearly all over the far West, and along the sandy stretches of New Jersey and North Carolina, and even Canada, which now seem incapable of supporting vegetation may, where the lands are thoroughly drained, become valuable fields when seeded to alfalfa. Perhaps in Utah, Colorado, New Mexico and Arizona alfalfa does its best along the honey-yielding line. The best grades of alfalfa honey are hard to excel.

Illinois Foul Brood Bill.—Jas. A. Stone, Secretary of the Illinois State Bee-Keepers' Association, has sent us a copy of the Bill offered in the Illinois Legislature for the suppression of foul brood. It is House Bill No. 103, introduced by Representative Kumler, of Sangamon county, and reads as follows:

AN ACT FOR THE SUPPRESSION OF FOUL BROOD AMONG BEES IN ILLINOIS.

SEC. 1. Be it enacted by the people of the State of Illinois represented in the General Assembly that upon the recommendation of a majority vote of the members of the Illinois State Bee-Keepers' Association, the governor shall appoint for the term of two years, a State inspector of apiaries, who shall, if required, produce a certificate from the governor, that he has been so appointed.

DUTIES.

SEC. 2. The inspector shall, when notified, examine all reported apiaries, and all others in the same locality not reported, and ascertain whether or not the disease known as foul brood exists in such apiaries; and if satisfied of the existence of foul brood, he shall give the owners or caretakers of the diseased apiaries full instructions how to treat said cases as in the inspector's judgment seems best.

DESTRUCTION OF BEES.

SEC. 3. The inspector, who shall be the sole judge, shall visit all diseased apiaries a second time, and if need be burn all colonies of bees, and combs that he may find not cured of foul brood; and for colonies so burned by the inspector, the owner thereof shall be paid not to exceed three dollars for each colony of Italian bees or hybrids, and not to exceed two dollars for each colony of black bees; to be paid the same as other expenses herein provided for.

VIOLATIONS.

SEC. 4. If the owner of a diseased apiary, or appliances, shall sell, barter, or give away, any bees, honey, or

appliances, or expose other bees to the danger of said disease, or refuse to allow said inspector to inspect such apiary, honey, or appliances, said owner shall, on conviction before a justice of the peace, be liable to a fine of not less than fifty dollars (\$50), nor more than one hundred dollars (\$100), or not less than one month's imprisonment in the county jail, nor more than two months' imprisonment.

ANNUAL REPORT.

SEC. 5. The inspector of apiaries shall make an annual report to the governor of Illinois, giving the number of apiaries visited, the number of diseased apiaries found, the number of colonies treated; also the number of colonies destroyed by fire, and his expenses.

EXPENSES.

SEC. 6. There is hereby appropriated out of any moneys in the State treasury, not otherwise appropriated, a sum not exceeding seven hundred dollars (\$700) per year, for the suppression of foul brood among bees in Illinois. Said inspector shall receive four dollars (\$4.00) per day, and traveling expenses for actual time served, which sum shall not exceed the moneys hereby appropriated, to be paid by the State treasurer upon warrants drawn and approved by the governor.

SEC. 7.— This Act shall take effect, and be in force, from and after its passage and publication.

Mr. Stone, when sending us the foregoing copy of the proposed law, added these words, that Illinois bee-keepers should heed:

If bee-keepers who know the harm of foul brood wish a law to protect them against it, let them write to, and talk with, their representatives and senators (as we will have the same Bill before the Senate), for there is no Bill that goes through without work, especially that has an appropriation attached. If our bee-keepers' executive committee comes before the appropriation committees of the House and Senate, and none of them have been approacht by their constituency, our work will be hard, and probably a failure. If it is worth having, it is worth working for.

Disinfecting Foul-Broody Honey.—Mr. J. B. Adams, Bee-Inspector for Boulder Co., Colo., uses the following method for disinfecting foul-broody honey for feeding back:

"Boil the honey hard for 20 minutes after adding 1/2 water. Let it get cold, and then boil again for 20 minutes. Foul brood spores have two skins; the first boiling and cooling loosens the first skin; the second boiling and cooling kills the spores."

THE G. B. LEWIS CO., of Watertown, Wis., have issued a very neat 1899 catalog of their apianian supplies. They are one of the very best concerns in all this country. Wisconsin seems to be noted for its bee-supply firms. And, so far as we know, they are all good ones, too.

MR. GEO. SPITLER, of Crawford Co., Pa., speaks thus of this journal:

"Say, do you know that the American Bee Journal is fine? The last number (Jan. 12) is just full of good things—so much really original matter."

DR. PIERO, whose office is in Central Music Hall, in this city, makes a speciality of throat and lung diseases. Any of our readers may feel free to consult him by mail, not forgetting to enclose stamps, of course. He has what is called the American oxygen treatment for lung trouble that he claims is a fine specific for la grippe and similar troubles. Just write him for his circular on the oxygen treatment, and mention the American Bee Journal. Don't be afraid to write him fully concerning yourself, if you wish.

DR. J. P. H. BROWN, of Richmond Co., Ga., wrote us Jan. 20:

"I am just getting over the la grippe—have had a hard time of it. The past season has been an 'off' one for the busy bee. I don't think 2,000 pounds of honey, all told, have been taken inside of a radius of 100 miles of this place. Result: Hundreds of colonies will 'go up' before next spring, unless fed. In fact, the loss already has been very heavy."

We are glad to know that our good Southern friend is all right again. La grippe is a terrible enemy to human health and happiness. We are just now (Jan. 23) suffering from a severe attack of eczema. Last week it covered the middle of the body, and now it is in the face and head, particularly around the eyes. It makes us almost sightless, and at night sleepless. We now know how to sympathize fully with any person suffering with eczema.

MR. G. M. DOOLITTLE, of Onondaga Co., N. Y., spoke on bees and honey at a farmers' institute near Syracuse, Jan. 18. Altho the "great lights" of New York State were there, and ex-Gov. Hoard, of Wisconsin, Mr. Doolittle, we understand, was as well received as any. Of course he would be, for he's a fine off-hand speaker, as was shown at the Buffalo convention, where he gave a splendid address. Mr. Doolittle and Rev. E. T. Abbott we believe are among the readiest public speakers of all the bee-keepers that we know. No one would ever go to sleep under the sound of their voices. Both of them ought to be kept in institute work a good share of the time, on the subject of bee-keeping.

THE MASCOTTE INCUBATOR CO., of Bedford, Ohio, report that they have been barely able to keep up with their orders by running their factory at its fullest capacity, and night and day. The Mascottes are standard machines of the hot-water type, and are finisht in the highest style known to the art. In hatching and brooding they leave nothing to be desired if we are to judge by the testimony of those who have used them, and should therefore know them best. Write these people for their new catalog, which gives full details of construction, etc. Also mention this journal when writing them.

ALFALFA OR BASSWOOD HONEY we can still supply as per our advertisement on page 94. There should be the best demand of the year for the next few months, and bee-keepers should supply it. Canned fruits will be running out in many a household, and honey will come in as a great help to the housewife. We can make prompt shipment at the prices quoted. Better try a two-can order, hadn't you?

DR. A. B. MASON, Secretary of the United States Bee-Keepers' Association, is already working on the program for the 1899 convention to be held in in well, we don't know just where yet, but it will be in some good place. We were going to say in Philadelphia. And the program will be a good one, too. The big Doctor knows just how to build it. He's had lots of experience "along that line."

MR. E. E. HASTY, of Lucas Co., wrote us Jan. 21 that he was "nursing a stubborn case of la grippe." This has been another winter when that heartless enemy has had things pretty much his own way in many localities. We hope that he will not deplete the ranks of bee-keepers. They can't be spared just yet.

MR. O. O. POPPLETON, of Dale Co., Fla., writing us Jan. 18, said:

"Bees are gathering some honey, and commencing to build up. The winter so far has been very mild, more so than usual, the thermometer indicating from 70 to 85 degrees every day for weeks past."

MR. F. F. ZILLMER, of Grant Co., Wis., writing us Feb. 1, said:

"The weather has been intensely cold the past three or four days—it is 25 to 28 degrees below zero."

The Premiums offered on page 62 are well worth working for. Look at them.

A Slatted Separator for Inset Sections being demanded, the A. I. Root Co. are preparing to meet the demand.

Large or Small Hives. according to A. E. Manum, in American Bee-Keeper, is a question for each one to decide for himself. The Dadants are right in using large hives, and G. M. Doolittle is right in using small hives.

Painted Hives are preferred by C. Davenport. They keep in good condition for 20 years, while unpainted ones begin to decay in seven or eight years. He does not believe with Doolittle that bees do any better in unpainted hives.—Bee-Keepers' Review.

Peppermint Honey as gathered in the West is reported, in the Progressive Bee-Keeper, as "curious looking stuff." Of excellent flavor, "but the cappings have exactly the appearance of moldy combs, even on the closest inspection by the naked eye; and yet there is no mold about it."

Honey Carried from Brood-Nest into Sections. At time of fruit-bloom, E. A. Daggitt gave each colony a super of partly-finished sections. At the close of fruit-bloom quite a little surplus was found in the sections, but it proved to be buckwheat honey, showing that it must have been carried up from the brood-chambers.—Bee-Keepers' Review.

Big Hive-Entrance for Winter.—Mr. Ruffy formerly closed carefully all cracks and openings in his hives, made the entrance as small as possible, and yet each spring he found moldy combs, spoiled stores, numerous cases of diarrhea, queenlessness, etc.; while at the present time with entrances open full width, and colonies ready for winter by the middle of August, he has excellent results.—Muenchener Bztg.

Winter Feed. "We often get inquiries on how to make a bee-candy for a winter feed when combs of sealed stores are not to be had. The best candy is the Good or Scholz, and is made in this way: Mix sugar and honey into a stiff dough; allow it to stand for a couple of days in a warm place and then knead in more sugar. Granulated sugar may be used; but powdered, or, better still, confectioners', is much better." Gleanings.

Tall Sections are Finished Faster and Better at the sides than square sections, says R. C. Aikin, in the Progressive Bee-Keeper. In comb-building, combs always progress much faster downward than sidewise, so the square section is finished down the center before at the sides; while the tall section will be finished farther down and stand transportation better. For this reason he also favors bottom starters for any sections that are to be shipped.

Wax Sticking and Cracking. Dr. Miller having directed to wet a wooden mold to keep wax from sticking to it, I. W. Beckwith says, in the Bee-Keepers' Review, that no amount of wetting or soaking will do if the wax is put in very hot and allowed to cool slowly. He sets the vessel of caking wax, when convenient, in ice-water, and if it shows a tendency to crack, as it seldom does, he runs a thin knife-blade half an inch deep between the wax and tin.

Foul Brood. G. Sawyer tells, in the British Bee Journal, how he uses the McEvoy method of curing foul brood. He thinks it an advantage to give young queens, and does not agree with Mr. McEvoy that it is needless to disinfect the hive. He says:

"My method of procedure is first to examine the hive, and, if found affected, I do nothing else in the apiary that day. Meantime, I make some rough frames, in which strips of foundation about 1/2-inch wide are fixed. After the bees have ceased flying for the day, I go to the hive, shake off all bees from the combs and replace with the frames fitted with starters. The diseased combs and frames are then promptly

burnt, which, when burnt out, have a bucket of water—to which a plentiful supply of carbolic has been added—thrown over the ashes. This is important, because the honey, when getting hot, is apt to run, and if in the vicinity of other bees, they will be sure to get at the melted honey and carry it off to their hives. The bees under treatment remain on the starters for three days, during which time no food is given. On the expiration of the three days, the bees are shaken off the 'starters' into a clean hive on as many full sheets of foundation as they will cover, and fed up with some good syrup medicated with naphthol beta. By this time they will appreciate the food, and, with me, bees so treated soon work up into a strong colony. Finally, the old hive is disinfected as recommended in the 'Bee-Keepers' Guide-Book,' and the frames of starters together with all old quilts burnt."

Formic Acid for Foul Brood.—Foul brood appeared in the apiary of J. Pontonnier, and the editor of Revue Internationale advises him to try formic acid. He took 100 grams of water, 100 grams of 25 percent formic acid, and 50 grams alcohol, thus making a 10 percent solution of the acid. He used 100 grams of this solution upon each colony. Without brushing off the bees, he sprayed each comb with an atomizer, thoroughly going over everything, unsealed as well as sealed brood, and cells containing honey, excepting no part. Three such treatments, perhaps a week apart, seemed to leave the colonies in health. But authorities in this country have little faith in drugs. A rather discouraging thing for drug treatment is that while cures are frequently reported across the water, there is no persistent settling down to any one remedy as successful.

Pressure for Wax-Extracting is advocated in the Bee-Keepers' Review. The editor thinks the man who renders old combs in the solar extractor losses 1/2 or 2/3 of his wax, with steam 1/3 is lost, and with boiling 1/4. I. W. Beckwith, by means of a squeezer made of two planks hinged together, got the wax out so entirely that the residue was dry and mealy instead of being the usual hard cake of slumgum. F. A. Gemmill took 21 pounds of slumgum left by the steam process, and by boiling and putting through a screw-press he got seven pounds of the finest wax. With the press he got from eight Langstroth combs three pounds of wax, one-half of which had perhaps been given in the foundation.

Bee-Escapes Are Not Liked by Mr. Bruce for extracting-supers, because they allow the honey to get cold for extracting. For comb honey he prefers to pile supers 10 or 12 high "with a generous light-admitting screen-escape arrangement on top." F. L. Thompson failed with the same arrangement, using it late in the season when bees are sluggish.—Progressive Bee-Keeper.—Mr. Thompson will probably succeed if he sets his piles in the hot sun, especially if bees are busy.

Work for the Bee-Keepers' Association. If the beekeepers of this country would support the United States Bee-Keepers' Association to the necessary extent to enable it to permanently engage an expert salesman, whose business it would be to develop a demand for honey put up and guaranteed by the Association under its official trade-mark, we firmly believe that every member who produced 100 pounds of honey annually would derive, in increased price, the cost of membership.—American Bee-Keeper.

Lumber for Sections.—Editor Hutchinson, of the Bee-Keepers' Review, says a man must use "a mighty deal of nice consideration" before he turns out a first-class section. In the matter of timber alone there must be great nicety. The wood of old trees is too dark. Only young, thrifty trees yield white wood. It must be cut in winter when the timber is frozen, and must be sawed before it thaws, for if sawed when not frozen it will be of a dark cream color. Spring must find the little, short planks piled up, but not too closely, or it will mildew.

The Secret of Well-Filled Sections. Editor Hutchinson (Bee-Keepers' Review) seems inclined to think something that has yet eluded our grasp. Better filled sections have been claimed for fences, because there was freer communication. Editor H. agrees with E. A. Daggitt that, on that basis, the best filled sections ought to be those secured without separators, but expresses his conviction that "combs are more perfectly attached to the sections when separators are used than when none are in use." No doubt a good many will hold a different view.

Root's Column

It seems to be generally admitted that a means for producing compression on sections when in the super is desirable, and some go so far as to say it is a necessity. If sections and separators are placed in supers loosely, it leaves little interstices or spaces that the bees fill up with propolis. Various devices have been used to bring about the desired compression. Some prefer and use thumb-screws; others, wedges; and still others, tightening-strips. Thumb-screws stick out in the way, and sometimes in damp weather become stuck fast in the holes. Wedges are very often propolized fast, making it difficult to remove them. The same objection applies to tightening-strips, altho to a less extent. We now use two or three springs to our 1899 supers, one at each end, bearing against the ends of the fences, and one in the center. See S in the cut below:

These springs produce a gentle, even pressure against the contents of the super; and, no matter how much the weather changes, causing the stuff to shrink or swell, these springs will produce always a gentle yet firm pressure. After the sections are filled they can be easily taken out, owing to the fact that there is a yielding pressure; and propolis well, it has no show.

In the next Bee Journal we will show you how these springs are applied. Meantime -

KEEP YOUR EYE ON THIS COLUMN,

The A. I. Root Company
MEDINA, OHIO.;

GENERAL ITEMS

Bees Helped the Fruit.

I got 900 pounds of honey from 90 colonies of bees this year. Prospects were good in the spring, but the honey crop failed to materialize. My apple and peach orchards paid quite well, which is partly owing to the services of the bees in pollinating the bloom. This was an incidental benefit fully equal to what they could have done storing honey in a good year. D. L. FILES.

Monroe Co., N. Y., Dec. 21.

A Fairly Good Season.

This has been a fairly good season for bees. There was no early or white honey stored above, most of the surplus being gathered in August from smartweed or lady's-finger. Honey is about the same price here as it was last season.

FRANK L. GOSS.

Vernon Co., Mo., Dec. 26.

He "Blames" the Bee Journal!

My bees did very well this year. I had 15 colonies, spring count, and got about 1,200 pounds of honey, part extracted. People want to know how the bees get so much honey in the city. I tell them it is not the locality, but the American Bee Journal that does it. M. M. RICKARD.

Erie Co., N. Y., Dec. 26.

Fears Hard Winter for Clover.

My bees are quiet with a temperature in the cellar of 43 degrees; outside, zero weather, with but little snow on the ground. I am afraid this will be hard on white clover; still, let us not borrow trouble.

WM. M. BARNES.

Richland Co., Wis., Dec. 27.

Bees Didn't Do Much.

Bees did not do much here last season. I have 50 colonies on the summer stands, and had to feed part of them before packing them for the winter. They had a good flight to day, and all appeared in good condition. The prospect for the coming season is good.

G. C. ALLINGER.

Marion Co., Ohio, Dec. 29.

Beginning with Bees.

I could not think of keeping a colony of bees without the American Bee Journal. I am a beginner, with four colonies, which did poorly the past year, but I am not discouraged, as they were bought late in the season, just after the linden flow.

Richland Co., Wis. Mrs. F. C. PENNELL.

Bees Did Very Well.

My bees did very well this year. I got about 4,000 pounds of comb honey from 92 colonies, spring count, and increased to 150, half of which I put into the cellar; the others I am wintering in a house lined inside and packed with leaves. I wintered some 25 colonies last winter in the same place, and they came out all right.

Iowa Co., Wis. WM. J. HEALY.

Season of 1898 Bees and Colors.

The bees came out of the cellar in the best condition I ever saw them in 1898. I had 130 colonies, all strong and healthy. It was a hard spring on the bees, and by the time the white clover bloomed they were weak in numbers. I got 1,200 pounds of basswood and white clover honey mixt. The basswood is five miles away. I got a little over 2,000 pounds of buckwheat honey.

SWEET CLOVER

And Several Other Clover Seeds.

We have made arrangements so that we can furnish Seed of several of the Clovers by freight or express, at the following prices, cash with the order:

| | | | | |
|-----------------------|-----|-------|-------|-------|
| Sweet Clover mellilot | 50c | 10lb | 25lb | 50lb |
| Alsike Clover | 60c | 21.00 | 32.25 | 54.00 |
| White Clover | 70c | 1.25 | 3.00 | 5.75 |
| White Clover | 80c | 1.40 | 3.00 | 5.00 |
| Alfalfa Clover | 60c | 1.00 | 2.25 | 4.00 |
| Crimson Clover | 55c | .90 | 2.00 | 3.50 |

Prices subject to market changes.

Add 25 cents to your order, for cartage, if wanted by freight.

GUS DITTMER, Augusta, Wis.

Please mention Bee Journal when writing.

I moved 41 colonies and ran them for comb honey, getting 1,000 sections. I got only 10 new swarms this year.

I see this question was asked in the Bee Journal if bees would sting black any quicker than any other color. I find on Sunday if I go in the bee-yard with a black hat on I am apt to get stung, when if I put my straw hat on they don't bother me. They don't mind the Sunday clothes if I have my old hat on.

Bees will store just as much honey without a bee-paper, but I think it pays me to take two. CHAS. BLACKBURN, Buchanan Co., Iowa, Dec. 28.

Honey Crop a Failure.

I have 42 colonies of bees in fine condition for winter, packed with chaff in the new Champion chaff hive. My bees are nearly all 5-banders. Our honey crop was a failure the past summer, but I hope for a better season to come. H. C. CLYMER, Linn Co., Iowa, Dec. 27.

Bees Light in Winter Stores.

My bees are tucked away in winter quarters, but I am afraid some of them will get hungry before spring. I fed some, but I never put bees in as light before. I hope we shall not have another such season soon. J. C. ARMSTRONG, Marshall Co., Iowa, Dec. 28.

Reports for Two Seasons.

I have 80 colonies in my apiary. I got about 3,000 pounds of honey last year, and about 2,500 this year. S. M. JONES, Norton Co., Kan., Dec. 22.

Bees Did Fairly Well.

Our bees did fairly well on white clover and basswood the past season. The fall flow was light. I had 87 colonies when the honey-flow began; at the close of the season 136, then doubled down to 111. I would have put them down to 100 if the weather had kept warm. My honey crop was 2,800 pounds. JOHN TURNELL, Houston Co., Minn., Dec. 7.

Seem to be Wintering Well.

My 98 colonies of bees seem to be wintering all right, so far. They had several good flights last week, and seem to be in good condition. W. S. FEERACK, Nicholas Co., Ky., Dec. 26.

Slim Honey Crop.

We had a very slim crop of honey here this year. During the white clover bloom it rained all the time, and the bees stored none. I never saw basswood so full of bloom, both great and small trees, but the bees only seemed to look at an occasional one. I got no honey except late fall honey, and but little of that, but I could hardly expect much, for I started in last spring with one colony of blacks and four Italians, and increased to 20, besides two swarms went away. The increase all came from the Italians; they filled their hives in a short time, and then went to swarming. I could only stop them by injunction. J. M. CLOCK, Wood Co., Wis.

Report for 1898.

I do not want to get along without the "Old Reliable" as long as I can get the "necessary evil" to help keep it going. I look for a better paper for 1899 than the past year, as it has been improved every year since I became a subscriber.

Stick to the spelling reform. Others will follow the good example in time.

I started the past season with 8 colonies, bought one new swarm, and increased to 20 colonies, taking 500 pounds of No. 1 comb honey, besides 50 unfinished sections. The

Please mention Bee Journal when writing.

bees are all in the cellar, with a good quality of stores, but some are short.

There was no fall flow here, and owing to rush of other work feeding was neglected until too late. "Poor management."

O. B. GRIFFIN.

Aroostook Co., Maine, Dec. 31.

Bees Did Poorly.

My bees did poorly. From 11 colonies I got 300 pounds of comb honey. The bees are in good condition, with plenty of stores. I winter them out-doors.

J. C. SMAL, Hancock Co., Ind., Dec. 26.

Poor Season for Bees.

I have been in the bee-business about three years, and have now 70 colonies in a house, all in first-class condition. I put in the house last winter 45 colonies, and took them all out last spring in good shape; but it has been a bad year with me here, as in the blossoming season it rained all the time, and then it came off so dry that there was no moisture in the flowers, and clover all dried up. So I did not get much surplus honey, and left me with about 1,000 sections with starters in them.

I am in a good location as there are not many bees within miles of mine, and plenty of white clover. FRANK VAN DYKE.

Greene Co., N. Y., Dec. 23.

Not a Prosperous Season.

My bees did about the same as a good many others—from 24 colonies I got about 600 pounds of comb honey, not quite one-third as much as I got last year. There seemed to be plenty of clover, but the bees did not work on it, and it was the same with buckwheat. But I will try to have them do better in 1899.

J. H. LOGEMANN.

Worth Co., Iowa, Dec. 28.

The Land of Rain.

This land of flowers, the past few months, could appropriately be called the land of rain. There has been down-pours, showers and real trash-movers since August last, and one time there was some rain fell every day for 30 days. So much fresh water running into the bay caused the death of shell-animals, such as oysters and conchs.

Roses are blooming, and bees find something to do in the ti-ti thickets. The growth of underbrush is so thick that it protects flowers from frosts, which so far have been light.

Honey in sections is selling for 10 cents a pound, or three pounds for a quarter. Honey gathered from saw-palmetto is thought to possess medicinal virtues.

Mrs. L. HARRISON.

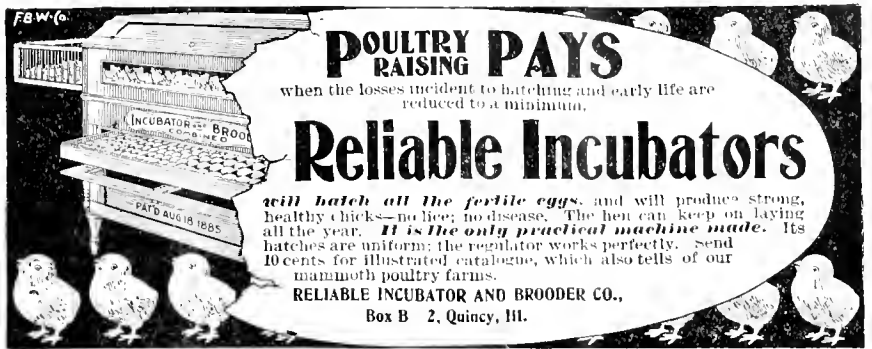

Washington Co., Fla., Jan. 2.

Bee-Stings and Rheumatism.

There has been so much said on the subject of bee-stings and rheumatism that it is useless for a man of my calibre to try to add anything new, but after reading the discussion on page 812 (1898) I am led to state a few facts, and facts or the truth is what every one should seek.

I was born April 30, 1824, consequently I will be 75 years old next April. In 1862 I enlisted in the service of my country, and served three years; during that time I contracted rheumatism, from which I have suffered ever since. I have been confined to my bed for a month at a time; at other times I could not lie down for a week, and all the sleep I got was in a rocking-chair by a warm stove.

Since 1880 I have received \$5.00 per month pension. My rheumatism has brought on heart disease of a very dangerous nature (a hardening of the valves), for which my pension was increased two years ago to \$17 per month. During this time, since I was 17 years of age, I have worked among honey-bees almost every season, and have been

POULTRY RAISING PAYS
when the losses incident to hatching and early life are reduced to a minimum.

Reliable Incubators

will hatch all the fertile eggs, and will produce strong, healthy chicks—no lice; no disease. The hen can keep on laying all the year. *It is the only practical machine made.* Its hatches are uniform; the regulator works perfectly. stung times almost without numbers, both before and since I was troubled with rheumatism, and I never receive any benefit or obtained any relief from stings of the honey-bee; the severity of rheumatism has increased rather than diminish.

What is rheumatism, or rather, what causes it? I once askt a physician this question, and his reply was, "It is acid in the blood." An alkali neutralizes an acid, hence physicians administer potassium to neutralize the acid in the blood. Scientists tell us that the poison of the honey-bee sting is formic acid. Will one acid neutralize another? Those acids which were first recognized were sour, but now there are acids that have not this property. Is formic acid one of them?

Let us hear from those who know. I have known where rheumatism has left a man as suddenly as it came, without any bee-stings, as in Dr. Mason's case. I don't wish to make light of any man's opinion, that thinks he has been relieved of rheumatism by bee-stings, but I have no faith in it. But when doctors can't agree, how shall we know the truth? S. B. SMITH.
Millelacs Co., Minn.

From Away Up North.

I am very fond of the Bee Journal. Its patience and good humor are very refreshing. I have no bees just now, but intend to make another trial in the spring. I had one colony last year, but they all disappeared some way. I think the blackbirds, catbirds, toads or mosquito-hawks must have gobbled them up. I noticed some very large black crickets with feelers over two inches long, the bodies 1 1/2 inches, and big, round beads. I never saw anything bite themselves so quickly, and station themselves under the bottom board. But I only saw them attack dying bees, and I do not think they entered the hive at all. Perhaps they were only pall-bearers come to the funeral. THOMAS HENRY.
Muskoka, Ont.

A Report from Oregon.

Last spring we started in with nine colonies and increased to 14, but one of the old colonies was eaten up by worms. I got 300 pounds of honey last season. I intend to Italianize next spring. I have 11 cedar hives and two Eastern pine. I like the cedar better, as they are lighter. There were 750 tons of dried prunes shipped from within seven miles of me, and the bees did not bother when drying them.

I sowed some sweet clover in 1897, and last summer it grew from three to seven feet high. Some of it is in blossom now.

Our first frost was Dec 7, and we had cold weather till the 14th. There is no sweet clover except where we sowed it. The bees workt on it real well.

Our best honey comes from poison-oak blossoms. It is almost clear, and real thick.

Our bees have plenty of honey to winter on. The coldest it has been in the last six years here was 16 degrees below zero.

HERBERT PRUNER.

Douglas Co., Oreg., Dec. 20.

An Experience with Hives.

I have kept bees for some time and tried to learn something of their habits, and find that it pays to give them comfortable homes. I began about six years ago, and soon adopted the dovetail hive, using mostly 8 frames—a few 10. I attended the bee-congress at Atlanta during the Fair at that place, and met Mr. Danzenbaker, who showed me all about his hive, but I did not try it then. At the same time he met my friend, Dr. Copeland, and the consequence was, the next season Copeland adopted the Danzenbaker hive, and seems to be well pleased with it. Knowing Copeland to be a man that took pains to get out all the money there was in a thing, upon his recommendation I bought some of the same hives and have used them for two seasons, and I am sorry that I did so, as they are

BEST

EXTRACTED HONEY FOR SALE.

ALL IN 60-POUND TIN CANS.

ALFALFA HONEY.

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and neatly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

BASSWOOD HONEY.

This is the well-known light-colored Honey gathered from the rich, nectar-laden basswood blossoms in Wisconsin. It has a stronger flavor than Alfalfa, and is greatly preferred by those who like a distinct flavor in their honey.

Prices of either Alfalfa or Basswood Honey:

A sample of either, by mail, 8 cents; samples of both, 15 cents. To pay for package and postage. By freight—one 60-pound can, 8 cents a pound; two cans, 7 1/2 cents per pound; four or more cans, 7 1/4 cents per pound. Cash must accompany each order. If ordering two or more cans you can have half of each kind of honey, if you so desire. This is all.

ABSOLUTELY PURE BEES' HONEY,

The finest of their kinds produced in this country.

We would suggest that those bee-keepers who did not produce any honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere. "YORK'S HONEY ALMANAC" will be a great help in creating customers for honey. See prices on another page.

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.

very much more difficult to manipulate, and 2-5 of the bees went up into the super to rear brood. I think the brood-frame is too shallow, and if I were to change from the Langstroth depth, I would want one deeper rather than shallower.

I have also tried the tall section and I don't think it is any improvement over the regular size. Bees will enter and work sooner in shallow sections than in the tall ones, as I take it most bee-keepers will admit. This has been proven in more than one way. They will not work on deep extracting-frames when they will willingly do so in shallow ones.

I have tried the Golden method for comb honey, and find it doesn't give me satisfaction. I believe the best all-around hive for this country is the 8-frame dovetail hive, with plain sections and fence-separators. Polk Co., Tenn. M. T. FOUTS.

[We fear Mr. Fouts has hardly given any of the hives mentioned any very extensive trial. At least his experience is not all borne out by that of many others.—EDITOR.]

Poor Way to Begin Bee-Keeping.

Bee keepers sometimes have methods brought to their notice that are not taught in either the text-books or bee-papers; and judging from the results that followed the method adopted by Henry Weisse, of St. Paul, it has not much to recommend it to those about to start in the bee-business.

Having decided to join our ranks May 9, 1898, Mr. W. proceeded to the apiary of J. J. Scott, in this county, where he obtained 4 colonies (about the right number for a beginner), but neglected the slight formality of either getting Mr. Scott's permission or leaving any of Uncle Sam's shekels to compensate Mr. Scott for the loss of his property, with the result that Mr. Weisse was committed to the Hennepin county bastille on May 30, from which institution he was liberated on \$500 bail. The grand jury having found a true bill against him, he was tried in Minneapolis, Oct. 13, and sentenced to two years in the State's prison.

If Mr. W. had taken the American Bee Journal he would have known for \$1.00 just what it will cost him two years of "hard labor" to find out, viz: That he adopted a poor plan to begin with, and also that "the way of the transgressor is hard."

Hennepin Co., Minn. Wm. RUSSELL.

Bees Did Quite Well.

Bees did quite well this season in this section of country. I got about 2,000 pounds of extracted, and about 200 pounds of comb honey from 35 colonies, spring out.

I have 49 colonies in the cellar in fine condition. It is about 20 years since I first started in the bee-business, but I lost my start a number of times, but did not give it up as I liked the little bees too well to be without them.

I got my last start in 1892, when I went to the woods with my neighbor—an old bee-hunter—and found six swarms, which I wintered in first-class shape. I have been successful since that time with the exception of one year; we had a large supply of honey-dew which was death to the bees.

I have had a great deal of experience in hunting bees in the woods and transferring them to hives. I believe I can hunt bees with any man. If I want to have a pleasure trip I take my hunting outfit and start out.

Sauk Co., Wis., Dec. 26. J. A. DOERR.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, Jan. 9. The trade is not active in comb honey, many of the retail dealers being supplied with sufficient stock to meet demands for some time to come. Prices are quite steady with 13c for best white, off in color, etc., including amber grades, 10c; 12c; dark, 9c. Extracted 6c; 7c for white; amber and dark, 5c; 6c. Beeswax, 27. R. A. BURNETT & Co.

DETROIT, Jan. 2. No change in supply of honey as to quality, but prices are somewhat lower than last quotations, viz: Fancy white, 13c; No. 1, 12c; 12c; fancy dark and amber, 9c; 11c. Extracted, white, 6c; 7c; dark, 5c; 5c. Beeswax, 25c; 26c. M. H. HENR.

INDIANAPOLIS, Jan. 4. Fancy white comb, 12c; 12c; No. 1, 10c; 11c. Demand fairly good. Park comb honey is being offered at 8c; 9c with almost no demand. Clover and basswood extracted, 6c; 7c. Beeswax, 26c; 28c. WALTER S. POWDER.

NEW YORK, Jan. 20. Fancy white, 12c; No. 1 white, 10c; 11c; amber, 9c; buckwheat and dark, 7c. Extracted in good demand at unchanged prices. Beeswax rather quiet 27c; 28c. Trade in comb honey is quiet. White is pretty well cleaned up, but there is a large stock of buckwheat, amber and mixt, having accumulated of late, and in order to sell in quantity lots it is necessary to shade quotations. HEDRELL BROS. & SEGLER, INC.

BOSTON, Jan. 9. Fancy white, 13c; 14c; A No. 1, 12c; No. 1, 11c; light amber, 9c; 10c; buckwheat, no call. Extracted, white Northern stock, 7c; 8c; Southern stock, 6c; 7c. Beeswax, 27c. The demand for honey seems to have dropped out of sight during the holiday season, but now that is over we hope to see a better call for it. There is abundance of stock on hand and it now looks as if the expected shortage would not materialize. BLAKE, SCOTT & LEE.

SAN FRANCISCO, Dec. 28. White comb, 9c; 10c; amber, 7c; 8c; 9c. Extracted, white, 7c; 7c; light amber, 6c; 6c. Beeswax, 24c; 27c. There is very little extracted honey now obtainable, and of water-white the market is practically bare. Comb is still in fair supply, with inquiry for the same of a light order. Market is firm for extracted and steady for comb.

KANSAS CITY, Jan. 25. Fancy white comb, 13c; No. 1, 12c; amber, 11c; dark, 10c. Extracted white, 6c; amber, 5c; dark, 4c. Beeswax, 25c. C. C. CLEMONS & Co.

BEELING, Jan. 27. There is a little more activity in strictly fancy 1-lb. combs at 12c. The bulk of receipts of low grades sell at 10c, down to 7c, and in a few cases even less. A moderate amount can be sold every day. Extracted, 4c; 6c, according to quality. BATTERSON & Co.

CLEVELAND, Jan. 2. Fancy white, 13c; 14c; No. 1 white, 12c; 13c; A No. 1 amber, 10c; 11c; No. 2 amber, 9c; 10c; buckwheat, 8c. Extracted, white, 7c; amber, 6c; buckwheat, 5c. A. B. WILLIAMS & Co.

MILWAUKEE, Jan. 9. Fancy 1-lb. sections, 12c; 13c; A No. 1, 12c; 12c; No. 1, 11c; 12c; dark or amber, 8c; 11c. Extracted, in barrels, kegs and pails, 6c; 7c; dark, 5c; 5c. Beeswax, 25c; 27c. The condition of the market is favorable for shipments of honey, especially of best grades, which are in small supply. The sales are moderate, but we are expecting an increased demand and good trade this spring. A. V. BISHOP & Co.

4,000 Pounds is the guaranteed capacity of this wagon. It is equipped with **ELECTRIC STEEL WHEELS** with staggered oval spokes, broad tires, etc. It has single steel hounds front and rear. It's low load capacity saves an extra hand in hauling corn fodder, etc. A pair of these wheels will make a low wagon out of your old one. Send for free catalogue and prices. Electric Wheel Co. Box 16, Quincy, Ill.

CONTRIBUTED ARTICLES

No. 4.—The "Golden" Method of Producing Comb Honey Described.

BY J. A. GOLDEN.

(Continued from page 60.)

FIRST, then, is a properly constructed hive, either a new hive or a remodeled one, as previously described.

Second, a normal colony of bees.

Third, a good queen, and her wings clipped.

Fourth, when your colony casts a swarm pick up the clipped queen and let her run in the cage, as previously noted.

Fifth, remove the parent hive from its stand and place the two prepared supers with sections on the stand, then remove one of the sections from one of the middle rows of the top super, and insert the caged queen, setting the parent hive on top of the two supers. If a super was on the hive at the time of swarming, just leave it on, and return the section (taken from super) to the feed receptacle which always remains on top.

Now take from the little pocket in the back end of the feed receptacle the slate, and register the age of the queen, and date of swarming, and don't forget, when taking off surplus, to register the same. Return the slate, and cover up the hive, by which time the bees will have returned, finding their royal mother occupying new quarters, ample, clean and tidy, and at once commence work.

(I will note here that some have reported that the bees re-swarmed after returning the queen, but almost all afterwards reported that the queen-cell or cells had been overlooked, therefore I advise setting a zinc entrance-guard for two or three days after releasing the queen.)

Sixth, on the fifth or sixth day, in the evening, lift the frames from the hive one by one, and shake or brush the bees at the front of the hive, and examine closely, and if you want to return the queen destroy every cell and anything that looks like a cell, as I have found queen-cells with just the tip showing above worker-brood, and having the miniature cups plainly marked.

But if you want to supersede the queen, take your choice of cells, and pinch the mother-queen's head, having examined all the frames; and if you wish to reserve two frames of capt honey for winter or spring stores, take out the two outside frames and set or hang them in the fuming-box, and insert two dummies in their place, and put the parent hive on the stand, placing the two supers with the swarm on top of the parent hive; removing the queen and cage, insert the section that was previously set in the feed receptacle, and if a super was on the parent hive set it on top of the two occupying the swarm, and if having reserved two frames of capt honey, record it on the slate also, and

put on the cover, then the 5-inch rim and cover, and if the queen is to be returned let her run in at the entrance with two or three puffs of smoke.

The question has been asked why I recommend making this change in the evening. I do so because all worker-bees are at home, and by morning every worker knows her department, and all goes well. Should you make the change at noon, all the difference would be, the bees would be bothered quite a little while, so it is advisable to change in the evening.

Seventh—Now it must be remembered that a new swarm of bees will work far more energetically until they build up to a normal condition than at any other time, consequently one must not overlook this and neglect to supply colonies on this method with plenty of surplus room, so there are thousands of workers already, and thousands still coming in upon the stage of action; and as the queen has been deprived from depositing eggs five or six days, she has now an opportunity, as many cells await her; otherwise, if the bees have not plenty of storing-room they will crowd the queen out by depositing their nectar below, and thus deprive the

A View of the Golden Hive Perfected.

queen of her mission, then sulk into the swarm fever, and results will not be satisfactory. A little too much room is better than not enough. Of course, one must use judgment, also be guided according to the flow whether long or short.

Having been censured for being reserved in giving in-

formation on my method in former articles, I trust the foregoing will be ample, and so plain that all may test it; then, having kept a record, as previously noted, figure the difference between a colony on the Golden method and the best colony worked on any other method, and report results. Practical tests are the proper methods to test it, and not what Golden or any other bee-keeper says, before you put all your eggs in the basket at one time.

Also, I ask in making out a record, don't forget to consider the new hives, frames and comb foundation one would have to make or buy for other methods when hived in separate hives; also the cost of brood-combs and the honey they contain, etc. Then contrast that with the same number of colonies on the Golden method, and see which you prefer to follow. Then be happy while following it. Am I not fair in the proposition?

Again, when the flow begins to wane, keep taking out finished sections and keep filling in their places sections nearest finished, thus reducing the number of supers as fast as the outlook will admit, by which one can have nearly all sections finished, providing the flow is not cut short suddenly.

After the surplus receptacles are removed, and you have some sections nearly completed, place a super over the brood and fill up with sections to be finished, then place over it an empty super and feed receptacle on top, and put in it one or two sections having a small amount of honey in them, and see how quickly the bees will empty them and store in the sections below. Then you can keep increasing the amount to be carried down, and thus you can save much nice comb, and at the same time have more finished comb honey.

After the flow closes, remove all surplus receptacles, take out the two dummies, moving the two outside frames to the side of the hive, and insert two frames filled with comb foundation. When you prepare your colonies for winter, if those frames are full of honey, you have two nice frames of capt honey stored away for each colony. But if a fall flow comes, you will have four in place of two.

To prepare colonies for winter, make cushions of cheese cloth or any cheap material, and loosely stuff with any choice of packing, so as to completely fill the feed receptacle. Close the wire-cover, and pack all around inside of the 5-inch rim, and put on the outside cover, having previously screwed the combined cover down, closing the side-entrances at the top of the brood-body, and bottom side-entrances by turning the bottom-board rim upside down, and setting the hive on the rim completely closes the same at the bottom. Then adjust the expander to suit your climate.

The idea of this wonderful little piece of furniture—the contractor and expander entrance-guard was donated to the perfecting of my hive by Mr. J. S. Hartzell, of Pennsylvania; also the movable alighting-board, which explains itself, and which is a great saving of wide lumber in cutting. When using this movable alighting-board the bottom may be the same length as the top, thus very handy for packing in a wagon when moving to out-apiaries.

In conclusion, I here show a view of the Golden hive perfected, giving a glimpse of the combined cover in position, also showing how the expander is used. The screw-eyes are past through the saw-kerf, then the expander can be changed to any desired space, and a turn of the screw-eye secures it. It is a real blessing in a time of robbing—so handy and complete, and if you use the Golden method use the expander and the detachable alighting-board, if desired.

I have endeavored in this series of articles to make all plain. I could give many testimonials from honest beekeepers from various parts of the United States, speaking in highest praise of my method. I kindly ask the beekeepers throughout the world to carefully, and without prejudice, give my method, as described, a test by a practical manipulation during 1899, then report your findings, whether good or bad.

I take this opportunity to publicly return my thanks to the very many that have written me, from every quarter of the globe, so many kind wishes, all of which have been highly appreciated by me.

Morgan Co., Ohio.

The Omaha Convention Report ran through 14 numbers of the Bee Journal, beginning with the first number in October, 1898. Now we have on hand quite a number of complete sets of that report, which we will mail for just 10 cents each. That is, 14 copies of the American Bee Journal for only a dime. There are doubtless a good many of our new readers who will be glad to get that fine report.

Honey-Dew—An Experience With It.

BY J. A. NASH.

ON page 17, Prof. A. J. Cook writes on honey-dew, taking the ground that honey-dew is a secretion of insects, and doubts the assertion of the British Bee Journal that it is "a sweet juice that sometimes exudes from the surface of the leaves of trees and plants." For many years I was of the same opinion as Prof. Cook regarding this matter, but I have since changed my mind.

A few years ago this section of Iowa was blest (?) with a very heavy flow of honey-dew. I did not see it on anything but the hickory leaves, but was told it also appeared on the walnut. It made its appearance only on the upper side of the leaves. Every leaf had many small, glistening drops of a sweetish substance on it. The bees would leave the hives at daybreak, and continue working until the heat of the midday sun had partially dried up the leaf juice, then work ceased; late in the afternoon they would often commence again and continue until nightfall.

I never saw as great activity in the apiary as at this time. The home apiary was situated near a heavy growth of small timber (and by the way, I never saw this "dew" on a large tree). This substance was very dark-colored, had a very rank flavor, and killed over 80 percent of my bees before the next spring, in a cellar that wintered my large apiary with a loss of about one colony in a hundred several times.

Now, I noticed this dew just as Prof. Cook says he did—from the back of a horse as I rode through the timber, and while I did not see any aphides, I had no doubt they were on the upper branches engaged in the manufacture of what some facetious writer called "bug-juice."

Now, undoubtedly, I should have believed to this day that all of the honey-dew in the country was caused by bark-lice had it not been for an old-time bee-keeper—one of the log-gum and brimstone regime—an old backwoodsman with a keen eye and a good supply of what Ben Butler called "horse-sense." He came into the apiary one morning as I sat watching the clouds of misguided bees as they fell heavily loaded on the alighting-boards, and wondered what I would do with the thousands of pounds of liquid filth (for it was not fit to eat) that they were filling the hives with, and remarkt, "Look a-here, old man; you told me that this honey-dew was made by bugs. Now, I just cut a black hickory tree that was covered with honey-dew, and they were not 40 lice on the hull tree, as I could find, and I allow I have two good eyes. Say, don't you think it was a sorter heavy strain on them lice to make all that dew? I allow they sot up nights."

The last remark a little sarcastically. I told my old friend that very likely the falling of the tree shook the aphides off, but concluded to investigate a little myself. This time I climbed the tree, in fact several of them, and the more I looked the more my faith in the bark and leaf louse theory was shaken.

On none of the trees examined could I find any insects except a few scattering, green-colored (very small) ones, such as can be found on hickory leaves at all times in warm weather. They are almost always found on the under side of the leaves, while the "dew" is on the upper.

A careful examination developt the fact that the leaves on the tops of the trees were covered as thickly as elsewhere, showing the theory that this substance was ejected from the bodies of insects did not bear a close inspection.

To make assurance doubly sure, I took a saw and cut off the top of a tree that stood about 100 yards away from any other timber, and observed this tree repeatedly. The tops of the upper leaves were covered as thickly as those on the lower branches. I also took a number of small limbs and placed them on the floor of the honey-house, carefully cleaning the tops of the leaves with a damp cloth. This was done in the evening. The branches were freshly cut, and no insects were visible. The next morning the dew could be plainly seen and tasted on these leaves, plainly showing that it was the juice of the leaves that from some cause burst forth and dotted them.

Now I don't wish to join issue with Prof. Cook. Honey-dew so-called may at times be caused by aphides, very likely it is, but I don't think that all the leaf and bark lice in Iowa could have made the honey-dew that was exuded from the leaves of Jasper county trees.

On this occasion there were tons of this stuff gathered by the bees, and the lice could not be found at all.

Jasper Co., Iowa.

National Pure Food and Drug Congress.

BY REV. EMERSON T. ABBOTT.

THE second annual meeting of this Congress was held in the city of Washington, D. C., Jan. 19-21. The program was an interesting one, and included some of the leading men of the Nation, among whom was the Secretary of Agriculture, and several other members of the House and Senate. The attendance was good, and the delegates represented almost every productive industry in the land. Scores of State and National organizations were represented, and they were nearly a unit in the belief that the passage of the Pure Food Bill as revised by the Congress last year should be urged without any material changes. There were some who thought the Bill could be strengthened by slight changes in the wording, and a few others, we are sorry to say, who wore the insignia of delegates, who were anxious to amend the Bill in order that they might kill it, but the Congress promptly sat down on all such movements.

A mark peculiarity of the Congress was its disposition not to encourage what is known as "class legislation." The bill as drafted a year ago is remarkably clear of anything of this kind, and it seemed to be the almost unanimous opin-

Rev. E. T. Abbott.

ion of the Congress that it should be left so. Here is one of the essentially weak points of many pure food laws—they are enacted purely in the financial interest of the producers, and generally of a single class of producers. Now, it seems to the writer that law has nothing to do with increasing the price of the produce of any individual or class of individuals, but it does have something to do with the interests of all of the people, consumers as well as producers. While the law has nothing to do with high or low prices, it does have something to do with preventing fraud and deception.

The Pure Food and Drug Congress is not asking that any industry be suppressed, or even crippled, but it does ask the Government to compel every man to sell his products for what they are, and that he be prevented from perpetrating any kind of fraud on his customers, as does every man who, prompted by greed and avarice, misbrands any article of commerce, or mixes any inferior or deleterious article with a food product. All of the addresses delivered before the Congress, with one or two exceptions, were along this line, and were keyed to this idea.

President Blackburn showed himself to be an excellent presiding officer, and, owing to his promptness and decision, a great deal of routine business was transacted, notwithstanding there were a great many addresses on the program. It was voted to make the organization permanent, a constitution and by-laws were adopted, and officers elected to serve until their successors are chosen. The old officers were all re-elected, it being the opinion of the committee on organization (of which the writer was chairman) that those who had begun the good work would better be left in full charge for the present.

It will no doubt be of special interest to the bee-keeping friends to know that our industry received its full recognition on the floor of the Congress the same as last year. The editor of the *Modern Farmer and Busy Bee*, who went as a representative of the United States Bee-Keepers' Association and the Missouri State Board of Agriculture, was made chairman of two important committees, and was again named as vice-president for the State of Missouri. Mr. Secor was continued vice-president for the State of Iowa; E. S. Lovesy, for Utah, and, at the suggestion of the writer, Thomas G. Newman was named for vice-president for California.

It will be seen from this that the bee-keepers will have themselves to blame if they do not have a hand in this important legislation.

We desire to say, in this connection, that the bee-keepers of the United States are under special obligations to the "Burlington," "Big Four," and the Chesapeake & Ohio railways, for it was through the courtesy of these roads that the delegate of the United States Bee-Keepers' Association was able to attend the Congress, there being only the small appropriation of \$15.00 set apart for this purpose by the Directors of the Association, and this amount would not pay hotel bills and sleeping-car fare, to say nothing about the other necessary incidental expenses. Therefore, we trust our friends will remember this, and show their appreciation of the favor by giving the roads mentioned above their patronage when opportunity offers.

We desire to say before we close that the Pure Food Bill was reported favorably by the Senate Committee during the time the Congress was in session. It was ordered printed, and a copy of it can be had by addressing the Senators of your State at Washington, D. C. The House Committee will also make a favorable report on it, we were informed, and the important thing now is for every one who reads this to write his Senators and Representatives from his District, and urge the passage of the Bill.

The Bill has found rather smooth sailing up to the present time, but it has now come to the danger line; its enemies are organized, and on hand with money and influence to defeat it. It stands in hand for every friend of common honesty, and pure food, drinks and drugs, to be on the alert and up and doing, that we may not lose the ground we have gained in our fight with this the arch enemy of mankind—the adulteration fraud.

Let us not be lukewarm; let us not be slow to act; let us not flatter ourselves that we are not personally interested, for we are. No man who eats or drinks can escape the baneful effects of this adulteration fraud, but if we are not interested for ourselves, it is to be hoped that for the good of humanity, for the good of our wives and children, for the good of generations yet unborn, we will shake off our lethargy, and go forward in our might to remove from the history of our country this cursed blight of fraud, deceit and duplicity, and that it may no longer be said that we are the only civilized country on the globe that permits the open and flagrant adulteration of foods, drinks and drugs.—*Modern Farmer and Busy Bee*.

Honey and Pollen Producing Trees.

BY F. A. SNELL.

AMONG the early-blooming trees that are planted for shade and ornament, the soft maple is probably the first to bloom in the Northern States. This tree yields a liberal amount of pollen, and but little honey. When the weather is mild during soft-maple bloom the bees are found humming the whole day long among the inviting blossoms, are stimulated to activity, brood-rearing is commenced, and the bees are much benefited.

This tree blooms, some years, very early, when a cold wave comes on after it has been in bloom two or three days, and the blossoms are frozen, and the yield of pollen and honey thus abruptly ends from this source. Had we years ago planted later-blooming honey-producing trees more extensively, and the soft maple not so much, our bees would have been benefited more. That matter should be more closely considered in the future in ornamenting our homes or home surroundings.

I have found the hard maple to be a true friend to the honey-bee, and well worthy of being planted by every bee-keeper and others who wish to secure one of our substantial trees. The hard maple yields a liberal amount of honey while in bloom, and blooms late enough so the weather is

generally good for the bees to work, and a great stimulus is given to brood-rearing where this tree grows in abundance.

The white or gray willow is also a later-blooming tree, and yields well in honey and pollen. It has been planted for windbreaks and shade quite a good deal, as well as for fuel. The bee-keeper who has been located near by has also been benefited. I have had strong colonies store enough honey while this tree was in bloom so the cells next to the top-bars in the brood-frames were filled with honey and sealed over. The weather was favorable during the blooming period, so the bees put in about every day. Only the observing bee-keeper knows what a pleasing condition this flow, coming before fruit-bloom, brings about in the filling of the brood-combs with honey, pollen and brood; and the amateur will almost daily open the hives to note the improved conditions daily taking place within his hives. "I have been there," to use a common phrase.

I would like to see the white willow extensively planted. It thrives well on moist land as well as upland, and can be grown on land not suitable for farming purposes. I believe a grove of these trees will pay good rent on most farms in windbreaks, fuel and protection to stock and field crops in general. The bee-keeper, at least, is hardly doing himself justice who neglects this valuable tree. The charcoal from this timber is considered with great favor.

In my locality the cherry and plum trees next come into bloom. For many years the planting of cherry-trees has here been much neglected, and where 25 years ago bushels of fruit were raised, now we may say that but little more than quarts are grown. This should not be so. Farmers and townsmen should study the different varieties of cherry trees, and select those that seem hardy and produce good fruit in near-by nurseries, and plant them. There are several varieties of these trees that fulfill the above requirements. There can be found room around almost every town home for the planting of a few of these trees, the fruit from which is most healthful.

The cherry-trees of our hardy varieties will grow on a variety of soils, and I doubt if any farm is so well occupied that room now not utilized cannot be found for the planting of from a dozen to two dozen trees. I feel free to assert that in northern Illinois not one farmer in ten raises his own cherries, and I believe the same to be true over a large part of our country. All bee-keepers should plant a liberal number of these trees and encourage their neighbors to do so by their own good example. The beautiful fruit seen growing on the trees of the apiarist would of itself have a good influence upon those passing along the highway when the ripe fruit was hanging upon the trees. The families would be supplied with fruit of their own instead of buying, as is too much the case with most farmers at present; and the honey-resources would be materially increased by the increased amount of bloom thus afforded. The trees may be planted along fences or upon sodland, or anywhere that one may elect to put them. They will do well when planted as near as 12 feet apart. Let every bee-keeper plant a few cherry-trees the coming spring. Carroll Co., Ill.

Starting with Bees—Hive Construction.

BY H. W. BECHLER.

FROM boyhood I had a natural longing for the honey-bee and bee-culture, but I never had the pleasure of owning any until three years ago, excepting some 12 years ago, when, on June 28, while working on a farm as a farm hand, I found a very small swarm of bees, not more than a quart in all, clustered on a limb of a little tree. I told the man for whom I was working that I was going to hive them, as it was good luck to find a swarm of bees. He had a big laugh at me, but with the laugh I got a nail-keg, and with a little trouble I hived them in it. Every day I would glance at my bees. I was very much surprised to see, after a few weeks, how fast they built up to a middling strong colony. As I did not know anything about bees, I then thought that another swarm came and went in with them.

In the fall, when the honey-flow was over, not knowing how much honey it would take to winter them, I supposed that they did not have enough to winter, so I killed them. But to my great surprise they had the nail-keg filled to the bottom. Then I was sorry that I killed them. This little experience only increased my desire to own and handle bees. But I never was situated so as to own any until a few years ago.

Three years ago this winter I traded a nice rocking-chair, which I made, for a colony of bees. The following

summer was a poor season for bees here, and, being very weak in the spring, they did not swarm, but stored about 15 pounds of surplus honey.

In the fall I bought another colony that was strong, in fine condition, and a good grade of bees.

The greatest problem that faced me in bee-culture was hive-construction. I made several different sizes before I settled on a style of hive that suited me. And while I had this problem before me, I commenced taking the American Bee Journal, and also commenced reading the "A B C of Bee-Culture." From these two useful helps I gained much information.

I use 1x10 inch lumber, generally in the rough, and by carefully dressing it I can gain a little in the thickness, probably leaving it 15 16x9 $\frac{3}{4}$ inches. With dressed lumber you hardly ever get over $\frac{3}{4}$ -inch thick. I cut the ends out of the thickest of the lumber, so as to have good, wide rabbets or shoulders for the frames to rest upon. I gauge the top edges of ends, letting the gauge rest against the outside, to 7/16 inch and rabbet from the inside, $\frac{1}{2}$ inch wide, to the gauge mark. The ends are cut perfectly square, and 13 $\frac{1}{4}$ inches long. This requires neat work. The sides are cut 21 inches long; this length includes 2 inches for a portico in front. The length of the hive-body proper is 19 inches on the outside. The front end is $\frac{3}{8}$ inch narrower than the back for a bee-entrance.

After the body is nailed together I cut down from the top of the portico 2 $\frac{1}{4}$ inches, and on these shoulders nail a water-table—a strip 2 $\frac{3}{4}$ inches wide by $\frac{7}{8}$ at one edge, and $\frac{5}{8}$ at the other.

I prefer loose bottom-boards. The cover is made of two boards 1x10 inches, with one edge beveled. These are nailed on two strips 3 inches wide, $\frac{7}{8}$ thick, and having a slope of 2 inches from the center of each strip, so as to form a roof.

These roof-boards should be nailed on these strips so they will fit neatly on the super and hive-body.

The super is the same length as the top of the hive, 19 inches, made out of $\frac{7}{8}$ inch lumber, thus giving a chance to tier up as high as desired.

And last of all the frames. The top-bars are 7 16x1x18 inches long, with a comb-guide tacked on the underside, or two three-cornered ($\frac{3}{8}$ inch wide) strips with foundation comb placed between these two strips, thus holding it perfectly tight, and at the same time giving strength to the top-bar. The ends or legs to the frames are $\frac{3}{4}$ x7 16x8 $\frac{3}{4}$ inches, and bottom piece is $\frac{3}{4}$ x7-16x15 $\frac{3}{4}$ inches, and nailed between the legs. All these pieces are cut in a cutting-box, thus making them exactly the same length, and also square at the ends. By this method the frames will be square and hang true in the hive. Super material can also be cut in a cutting-box.

But how to space the frames and keep them spaced was a puzzle to me; and after studying over the matter for a long time, and trying different plans, some one mentioned staples in the Bee Journal. That idea alone was worth \$5 to me. But it did not specify how to use them at that time. At first I tried to put them in the edge of the top-bar, but it would split the top-bar, so I tried putting them in the rabbet and spacing with a compass, and making holes with a brad-awl. I like this plan very well. Frames are easily taken out. I use 9 frames in my size hive.

This method will do only for those who are mechanics enough to make their hives, and have not much else to do in winter time, and a warm place to work in.

Keokuk Co., Iowa, Dec. 26.

York's Honey Almanac is a neat little 32-page pamphlet especially gotten up with a view to create a demand for honey among should-be consumers. Aside from the Almanac pages, the forepart of the pamphlet was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample for a stamp; 25 copies for 40 cents; 50 for 60 cents; 100 for \$1.00; 250 for \$2.25; 500 for \$4.00. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last. Better order at once, if you want a copy of this song.

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(Questions may be mailed to the Bee Journal, or to Dr. Miller direct.)

Basswood Two-and-a-Half Miles Away.

I want to move 40 colonies of bees to within about 2½ miles of a rich growth of river bottom with any amount of basswood on it. Can bees make a success at that distance?

IND. TER.

ANSWER.—I think you will find that bees will work well on basswood 2½ miles distant. I'd give a good deal for a lot of it that near me.

Moving Bees in Winter.

I have just bought a large apiary 17 miles from home. Would it do to take the bees from the cellar some fine day, and move them to my own at this season (Jan. 27)?

WISCONSIN.

ANSWER.—Yes, if the weather is fine enough for the bees to have a flight before being put into the cellar again. I shouldn't want to take them from one cellar and put them into another without a flight, unless pretty sure they would be kept in only for a short time. Some have reported doing so with no bad consequences, and if you care to take the risk yours might be one of the successful cases, but unfortunately there have been other cases in which the results were disastrous.

Likely Dying of Old Age.

Quite a number of my bees are dying; others on a fine day will come out, fly a short distance and drop dead. They have plenty of honey. What is the trouble?

OREGON.

ANSWER.—If the number is not large, there may be nothing wrong. In the course of the winter a great many bees die in every colony from old age, and when there comes a day warm enough for them to fly the healthy bees will carry out some of the dead ones and drop them on the ground, and some that are "on their last legs" will fly out and never return. It is quite possible that there is nothing wrong with your bees, so far as can be learned from your description.

Styles of Hives, Etc.

1. I bought a colony of bees last fall, size of hive as follows: 14x20, by 14 inches deep, outside measure, with 11 frames put in crosswise. What make of hive is it?

2. Are frames better lengthwise or crosswise?

3. On top of the frames was cotton stuck fast by propolis. I have them wintered outside packed in chaff. Should I have taken off the cotton before putting them away for winter?

4. Describe the different makes of hives, with their advantages and disadvantages. Being a wood-worker I could make my own hives, frames, etc. I would like to know about these hives: Langstroth, Dadant, Gallup, Heddon and Quinby.

5. What are the sizes of the Langstroth 8 and 10 frame hives? I see that make spoken of more than any other.

6. Which style of hive do you consider best for comb honey?

CANADA.

ANSWERS.—1. I don't know.

2. In this country most bee-keepers prefer to have the frames running toward the entrance, so that a bee on first entering a hive can go upon any frame.

3. It is generally considered better to have some open cloth like burlap in place of a cloth that is covered with propolis so as to be air-tight. Still, if the propolized cloth is warmly covered over, and the entrance is open enough, it will do very well.

4. In one sense all the movable-frame hives in the country are Langstroths, for he invented the movable frame. The name, however, when used in a more restricted

sense, is generally applied to hives with frames that do not vary much from 18 inches in length and 9 inches in depth. The Dadant and Quinby are the same, with frames of large size, 18½ inches long and 11¼ deep. The Gallup frame is 11¼ inches square. Heddon frames are 18 1-16 inches long and 5⅝ inches deep. They are not hanging frames, like the others, but are held in place by the pressure of thumb-screws. The hive can be inverted at will, and two or more stories are used at pleasure. All dimensions here given are outside measure.

To give all that has been said as to the advantages and disadvantages of these different hives would fill many numbers of the American Bee Journal, so of course it cannot be given here.

5. The frame generally used for the Langstroth or dovetailed hive is 17⅝ long and 9⅝ deep. For an 8-frame hive the body is 18¼ inches long, 12⅝ inches wide, and 9⅝ deep. For a 10-frame hive the width must be 2¼ inches more. These are inside measurements.

6. All things considered, I prefer the dovetailed hive, but there are good men who use successfully almost all of the other kinds. It is possible that what is best in one place may not be best in another, and in any case the man is more than the hive.

Some Northern Extracted Honey Doesn't Granulate.

In regard to all extracted honey granulating in the North when cold weather comes, we have some that was extracted in August, 1898, that is not granulated yet. It is kept in 5-gallon cans in our shop; it was well ripened when extracted, and is as good now as when first taken. By having a good quality of honey, we are able to get better prices than do most of them on our market. MISSOURI.

ANSWER.—Here's further evidence from a well known bee-keeper that not all Northern honey granulates in winter. I'm very glad that my ignorance in this matter has been exposed, and should be pleased to know of others who have kept honey in the North without granulation. I have an idea that the thorough ripening has something to do with it.

Queen-Excluders, Full Sheets of Foundation and Wired Frames in Extracting.

1. Should I use a queen-excluder between the brood-chamber and the super in producing extracted honey?

2. Should I use full sheets of medium brood foundation, or a starter, in the surplus frames for extracted honey?

3. Should extracting-frames be wired? IOWA.

ANSWERS.—1. Some do, some don't. Some object to the hindrance of the excluder to the work of the bees, but most think that of little account. Very likely the advantage of having a sure thing in confining the queen to her proper place more than pays for all trouble and cost. With my present light I should much prefer to use excluders.

2. On more than one account you will find it best to have full sheets so as to have straight worker-combs.

3. Yes, unless prevented from sagging in some other way, but if very shallow they may do without wiring.

Dampness in Hives—Early Breeding, Etc.

1. I find that some of my colonies have it very damp, the water hanging in drops under the cover and on all sides inside the hive. What is the cause and the remedy?

2. One colony has three frames nearly filled with brood, altho other colonies (seemingly in the same condition last fall) have scarcely any. I would like to know (a) Why this colony has so much brood at this time? (b) Would the queen be a good breeder? (c) Will this colony be ahead or better than others in the spring (provided, of course, that they live till spring)?

3. Will bees that take flight every three weeks or so consume much more honey than bees that scarcely take any flight through the winter?

4. I have a colony of pure Italians that will sneak around the entrances of other hives (even in chilly weather) and disturb them, causing them to be restless. What would I better do?

WASHINGTON.

ANSWERS.—1. Very likely your hives are closed up too tight. Moisture is being thrown off from the bees all the time, and if there are no facilities for its escape it settles

on the walls of the hive, just as in summertime the moisture of the air settles on the outside of a pitcher of cold water. Many think the best plan is to have what are called absorbents, that is, packing of some kind, over the frames so close that it keeps the bees warm, and at the same time so open that the moisture can escape up through the packing. There is not so much need of this if the entrance is large, and perhaps the best thing you can now do is to increase the entrance in some way. If it can be done in no other way, perhaps you can slip little wedges under the two front corners, raising the hive $\frac{1}{8}$ or $\frac{1}{4}$ inch.

2. (a) Possibly the same reason that makes the hives so damp may account for the unusual amount of brood. The bees are shut up too close; haven't air enough, and that makes them exert themselves trying to change the air in the hive, and anything that excites to activity may start breeding. Of course that's only a guess, without knowing all the circumstances. (b) It's not at all certain that she'll be better than others. (c) Probably the chances are that the colony will be no better than, if as good as, others.

3. Probably not a great deal more. The benefit of a flight once in three weeks will pay for the extra consumption.

4. Without knowing any more of the case, I should make a guess that one good way to get rid of the trouble would be to have all your bees the same as that one of pure Italians. When there is much robbing going on, it's not so much that the robbers are of bad habits as it is that temptations have been thrown in their way. The fact that those bees are hunting around even in chilly weather shows that they're not lazy, and very likely you'll find them good honey-gatherers. But they would hardly be fooling around much in the cold if the other colonies had always promptly repelled them. That colony is probably as wide-awake about defending itself as it is at trying to rob others. If all were like it, there would be little temptation to robbing, and in chilly weather all would stay at home and mind their own business.

ural causes, saying that he simply outgrows the enthusiasm of youth; but does that explain it all?

I think that to this habit of spending the best years of one's life in the pursuit of money exclusively, is largely due the veneration of work for work's sake, of mindless diligence, which is so constantly held before us by short-sighted moralists. They fail to realize that the enthusiasm afforded by spontaneous growth and activity is the highest possible incentive to diligence, and to the undertaking of just as much unnecessary drudgery, if not more, than the habit of mindless routine ever inspires, and that the man thus inspired never outgrows his youth.

But this must be practiced to become available. Training is required, just as truly in the one case as in the other. One cannot swim without entering the water. One cannot ride a bicycle by becoming a good horseman. The ability to discover and apply one's best powers, and put them to work, without the stimulus of getting something to eat, or the artificial aid of habitual routine, is a hard thing to learn; and like other difficult things, must be practiced early in life to acquire proficiency.

Not only is it hard to learn, but we do not even get the chance to learn it under ordinary circumstances. Society tells us the only work is to work for a living, or to work to get rich, and in accordance with this sentiment so manages that almost all occupations absolutely must be followed from daylight till dark, year in and year out, to be made a success of at all; and if we do not watch out, we will fall into the habit of believing this nonsense, and of regarding this condition of things as one of the laws of the Medes and Persians, which cannot change.

Right here appears the essential superiority of bee-keeping. It gives us a chance, not in the evening of life when well-nigh impossible, but now, to acquire the fullness of this attribute which distinguishes man from animals, this untrammelled freedom, this fresh energy, which comes from regarding one's self as an intelligent instead of a mechanical portion of the universe.

It is true, it does not give us the thing itself. It gives no more than the chance to acquire it; it gives the spare time, that is all. But, as I say, most other occupations do not give even this much.

Therefore, it behooves us to jealously guard this characteristic of bee-keeping from attack by the sordid and stupid mechanical spirit of the age. We do not want profit reduced to such a small margin that only capitalists can keep bees, when such numbers will be required as to keep one man hard at work all the year round, besides others during the swarming season. We want to keep this precious possession of leisure, freely given us without price in such abundant measure, as would require many years' toil of the best part of life to lay up enough to purchase.

Organization is the remedy for diminishing profits; and in our occupation it is to some extent also a remedy for diminishing leisure, by lessening the number of colonies required to make a living, and so removing the necessity for making hives and putting up sections all winter. But the fight is an unequal one. The price of honey is down now, and can scarcely be raised more than a trifle. Every method must be tried to prevent that bondage to false ideals to which so many other occupations have succumbed. The production of the most honey by the least labor is no less important than the sale of honey. Advanced methods and short cuts should be discussed just as much in our conventions as business questions.

Socialistic schemes are well enough in their way, but they do not go to the bottom of the matter. As long as money alone is worked for, and the opportunities of acquiring leisure without money are ignored, it will become harder to do anything without money. It is not true that men do not get what they strive for; they do get it, and with a vengeance. They set up unthinking industry as the ideal and then have the inconsistency to complain when the social conditions to which they have contributed react by keeping them at routine work the whole time. If they work as hard and as untidily for leisure as for money, they would get it.

Under present conditions, I think in most localities a man who sells his crop wholesale needs about 300 colonies of bees, in say three different apiaries, to make a fair living and have about five months of leisure, *i. e.*, unfinancial work.

Of course, the management of swarming in out-apiaries, in connection with getting as much surplus as possible, is the kernel of the matter. I will put it in the form of a concrete question, and if that can be satisfactorily answered, the question in general will be settled, and, inci-

CONVENTION PROCEEDINGS

Proceedings of the Colorado State Bee-Keepers' Convention.

(CONTRIBUTED BY THE SECRETARY.)

[Continued from page 87.]

THIRD DAY.

An Adequate Income from Bees by Seven Months' Labor Without Hiving.

I shall not answer this question, but leave it as uncertain as I find it. Nor shall I say anything original, but rather aim to put it suggestively, so that you may answer it.

Bee-keeping during the last few years has become less profitable. We say that organization is the remedy. It is, so far as financial returns are concerned. But when bee-keeping becomes less profitable, all its advantages, not only the financial ones, are threatened; and the great advantage of bee-keeping as an occupation is not so much the size of the money returns, as the fact that it contributes in a far more substantial and direct way than money does toward true riches.

The chief end of money is to purchase leisure; that is, the liberty to do what we can best do, without regard to the means of subsistence. Bee-keeping gives us leisure during a portion of each year without the necessity of hoarding up money to purchase it. The specialist bee-keeper with an income of \$300 a year is a richer man than the city physician or lawyer with an income of \$3,000. The latter may save money with a view to retiring sometime, and enjoying the fruits of his labor; but meanwhile the best years of his life are slipping away; his habits of mind become fixt, and when his liberty does arrive, he is nothing more than a cog in the social machinery the treadmill theory of existence has done its work. He is mentally crippled. He cannot work without supporting himself with the crutch of routine. He insists that crutches are a necessary portion of the human anatomy. We often refer this unnatural condition to nat-

dentally, much information elicited which will be valuable to the man with two apiaries or one apiary. The question is this: Can one man without any assistance do all the work inside of seven months of properly running 300 colonies in three apiaries for comb honey?

The answer to that question must not be based on any particular form of hive. We cannot afford, at present prices of honey, to buy new hives for the bees we have, or for the colonies we pick up here and there around the country, unless these are in very undesirable hives.

I have tried dequeening, but am not satisfied. It involves finding a great many queens, and cutting a great many cells, when time is very valuable. Besides, I want brood at that time, to rear workers for the second crop.

I tried a plan once for natural swarming on 15 colonies, and liked it very much, which I think could be readily applied to artificial swarming. Extra hives are necessary. The swarm is hived in the new hive on the old stand, and a day or two later the old colony set on top of the new hive and super, with a board between containing a little perforated zinc to allow the bees to pass up and down, and a bee-escape communicating with the outside to allow the drones and young queens to get out; and this upper story is kept there until all the brood hatches. That settles the question; there are no queens to find, no cells to cut, no after-swarms to hive, and the whole strength of the colony is kept together. I think it might be simplified by having no zinc or bee-escape in the board, but simply an outside channel, large enough for ventilation, connecting the upper hive with the entrance of the lower one. I have not tried the latter arrangement just for that purpose, but I have tried it on a large scale for a bee-escape, using a small channel, and it works well.

But the details of the plan are unimportant. That the principle is a success is shown by the experience of F. and H. Rauchfuss with a device by which the hives sit side by side instead of one above the other. The objection to this class of plans is that extra furniture is necessary. But from such experience as I have had with both, I like the idea better than dequeening.

In order to get rid of the extra devices, Mr. H. Rauchfuss now prefers a plan which he described in the convention last year, which came at such a time in the proceedings that it was not appreciated as it should have been. I will therefore briefly describe it as a representative of another class of plans, those which involve requeening:

Shortly before the honey-flow the queen and two frames of brood are put in an upper story with an excluder between, and the upper story filled out with empty combs. The vacancy below is filled with frames of brood and bees, taken from some colonies reserved for the purpose. Nine days after, the upper story is removed to a new stand, all queen-cells cut from the lower story, a virgin queen is given to the latter, and a super put on.

There are certainly no objections to the results of this plan; it is bound to be successful, and has been proven to be. But it involves finding of queens, cutting of cells, and queen-rearing. To be sure, the cell-cutting, in this case, is not a serious matter, for not so many bees are in the way as by the ordinary plan, and all cells are cut instead of all but one, so that the bees can be shaken from every frame. But 300 queens are to find, and 300 queens to rear. These are trifles for Mr. Rauchfuss, but I suspect many would be glad of a modification which would enable them to work in a little different way.

Finally, there is a class of plans which consists essentially of removing or shifting sealed brood. Mr. Hutchinson has told us in the Review how a bee-keeper of Michigan, Charley Koeppen, manages five apiaries of 50 to 75 colonies each on this plan, with the help of one man for about three weeks during the swarming season. This is not exactly what we want, for we want to know how to do it with no help. Few can afford to hire. But it may be suggestive. He puts empty combs in the center of the brood-nest just before the flow. A week or ten days later the combs of sealed brood in the center are shifted to the outside, and the outside combs, which are largely filled with honey, are moved to the center. Then at the beginning of the basswood flow he overhauls them again. I suppose if we were imitating his plan we would make it a week after the last round. This time he takes away two combs of bees and brood from all strong colonies, filling the vacancy with empty combs, and makes nuclei with the brood removed, giving each nucleus a queen-cell, of which there are plenty to be found in overhauling the colonies. All queens are clipped. With this management, Mr. Hutchinson says there is practically no swarming. Upon reaching an apiary, if

there is not time to go over the whole number of colonies, the strongest are selected.

Mr. Brock, of our Association, has followed a plan something like this for 20 years, and always secured good crops. However, he runs only two apiaries, and we want to run three.

Circumstances will probably compel me to adopt a combination of plans. The trouble with most of these schemes is that they require extra hives. As honey-prices now are, we cannot afford much even partially idle capital, in the shape of hives, not about every one occupied by bees all the year round. I cannot answer the question certainly in my own mind, whether an average man can run 300 colonies for comb honey without assistance, and do all the work inside of seven months. A few smart men do. Quite a number attend to two apiaries with ease. But I think there is a possibility, that by attentively considering and weighing all methods heretofore given, the average man may evolve one suited to his particular case, which shall be successful.

In order to help him out, I ask every one here who has had experience with out-apiaries to give the method which with him has proven most successful and consumed the least time; and not only that but to think and experiment about this matter during next season's work. It is one of the most important problems which confront modern bee-keeping.

F. L. THOMPSON.

Mr. Pease—Why that number in three apiaries?

Mr. Thompson—I put it that way merely to avoid bringing in the question of overstocking.

Mr. Foster—How many have made a success of non-swarming, that is, so that the swarms do not come out and alight on the trees?

Pres. Aikin—I have been managing three, four and five apiaries with a minimum of swarming.

Mrs. Rhodes—We had 60 colonies in chaff hives. We opened them early, and gave them plenty of room. The first season we had no swarms; the second season, three or four. We gave 24 frames altogether, and ventilated by raising the cover.

Mr. Foster—I have succeeded as far as I have gone, by watching, and when likely to swarm soon I either divided a colony or gave a large amount of room.

Mr. Adams—I have no particular method. It depends upon a great many things—room, ventilation, weather—getting bees to work in the sections is the main thing. Occasionally one can't control the swarming impulse.

A Member—When bees get warm, will it bring on the swarming-fever, without a crop of honey at the same time?

Mr. Adams—The bees get warm because they are crowded.

F. Rauchfuss—How do you give room?

Mr. Adams—Just by giving room—just adding more.

F. Rauchfuss—You must have a different strain of bees.

Mr. Adams—Yes, I have a non-swarming strain. I had 4 to 8 percent of swarms in the last seven or eight years.

Mr. Carlsen—I had 2 to 2½ brood-chambers to the colony. I took away all the sealed brood possible, and put on supers when the honey-flow came.

F. Rauchfuss—We have practiced dequeening, but did not like it. But we gave young queens or hatching queen-cells just before the inclination to swarm. It is hard to rear young queens at that time of year.

Mr. Pease—Did you destroy the old queens?

F. Rauchfuss—We kept the old queens as a reserve stock, in nuclei of one frame of hatching brood each.

Mr. Gill—I have not prevented swarming. I have 234 colonies in the home apiary, and two apiaries outside. One bee-keeper can attend to the work, but he has to have a wife. I make the strong ones swarm early, and have been successful, using the 8-frame hive. From every colony that shows an inclination to swarm I remove a frame, and let them build a little comb, and get them started in the super, and keep the bees engaged. Worthless queens are killed and others given. Starters are used indiscriminately. Supers are removed from one hive to another, with bees in them, so as to give the other bees an object-lesson, and show them they can keep at work, and empty supers placed on the hives they were removed from. I soon have all the bees at work in supers. Last season I had 30 swarms in the home yard. I have little faith in dequeening for comb honey, tho it is all right for extracted.

Philip Large—I do not try to prevent swarming, but have no more swarms than I need. I had 16 or 17 swarms from 195 colonies, mostly in 10-frame hives.

[Concluded next week.]

United States Bee-Keepers' Association.

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., E. Whitcomb; Vice-Pres., C. A. Hatch; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GEN'L MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

VOL. 39. FEBRUARY 16, 1899. NO. 7.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

The Extraordinary Yield of Honey-Dew in 1808, as reported from all over the world, is mentioned in a "straw" in Gleanings with the remark, "Perhaps honey-dew was no more plentiful than usual, but the scarcity of floral nectar made the bees store what in other years they neglect." To this the editor replies:

"Perhaps; but when there is honey in plenty from the fields, I have noticed that the sidewalks under the trees are not spotted by the spray of the honey-dew as they are during those times when honey is scarce. Is it not possible that Nature has so provided that, when nectar is not secreted in the usual way, because of certain conditions of atmosphere, those same conditions are favorable to the secretion of another form of saccharine matter, or, rather, to the growth of certain insects? You know there is a wonderful harmony in Nature. The all-wise Creator has in many ways made one hand to help the other."

Honey for Nervousness. In a German bee-paper is related the case of a lady who for nine years had been badly afflicted with nervousness and insomnia. One night after a liberal feast of honey she went to bed with her sleeping-powders near at hand, but she went to sleep, forgetting all about her sleeping-powders, not waking till the sun was up the next morning—a thing that had not before happened for years. Altho this might not happen in every case, there might be other cases in which the same results would be obtained.

The Pure Food and Drug Congress which met in Washington, D. C., last month, is an organization in which every honey-producer should be intensely interested. Mr. Abbott

gives an article on page 99 that should be read by all our subscribers. No better delegate than he could possibly have been sent to represent the interests of bee-keepers. We trust that Mr. Abbott may be able to attend every meeting of the Congress, and help carry through the Bill under consideration, which is of such vital importance to every lover of pure food—yes, of vital importance to everybody who has a stomach to put food into.

The officers of the National Pure Food and Drug Congress are these, whose names we count it an honor to record in the columns of the American Bee Journal:

President—Joseph E. Blackburn, Columbus, Ohio. 1st Vice-President—Frank Humé, Washington, D. C. Corresponding Secretary—Alex. J. Wedderburn, Washington, D. C. Recording Secretary—Franklin Dye, Trenton, N. J. Treasurer—R. N. Harper, Washington, D. C. Executive Committee—Dr. William Frear, State College, Pa.; W. S. Thompson, Washington, D. C.; L. M. Frailey, Camden, N. J.; F. J. H. Kracke, New York; W. A. Withers, Raleigh, N. C. President, First Vice-President and Secretaries are ex-officio members.

In addition to the above there is a Vice-President for each State represented, the District of Columbia, and one for the United States.

The Cylindrical Hive is one of the latest things in Europe. It looks something like a section of a log lying on its side, with four legs stuck into it—or like a barrel churn. It is about 2½ feet long and contains 20 circular frames, each comb being contained in a hoop having an inside diameter of 14 inches.

Box-Hives in France, as well as in Germany, are used much more than in this country. In a list of bee-books offered by L'Apiculteur, a prominent French bee-journal, 16 give instruction for box-hives and 15 for frame hives.

A Plea for Candied Honey.—There are some who prefer honey in the candied state, and Gleanings thinks this taste should be encouraged. The editor likes candied honey on bread and butter because he can "put it on thick." An employee with a mustache likes it because it doesn't smear his mouth so much. The editor says:

Suppose you try an experiment in your own family. Put three kinds of honey on the table; and if the candied has not been on the table for a month back, just see how quickly it will be taken in preference to the other two.

As you meet your customers, always mention your candied honey. Ask them to try a sample. You will be surprised to see how they will call for more.

I think the main reason why the candied article does not sell in the open market is because the average consumer imagines it is "sugared," or not pure in that form; but if he once understands that it is genuine, honest honey, we shall see a market demand for honey in that form in the markets generally.

Again the Comb Honey Yarn. This time it is the Farmer's Voice that is helping to injure bee-keepers. Mr. Walter S. Pouder, of Indiana, sent us the clipping, which we forwarded to General Manager Secor, who wrote at once as follows:

FOREST CITY, IOWA, Jan. 19, 1899.

TO THE EDITOR OF FARMER'S VOICE, Chicago, Ill. —

Dear Sir: I notice in your issue of Jan. 14, page 50, current year, this paragraph:

"It is almost impossible to buy pure honey. Even honey in the comb is adulterated. A syrup of glucose and dissolved sugar is fed to the bees, and they fill the combs as with honey, but it is inferior."

I am sorry that a paper of the recognized standing and ability of the Farmer's Voice should be the medium of extending a popular belief to the injury of a class of rural economists and co-workers in agricultural pursuits.

This matter of adulterating comb honey by feeding bees glucose is not new, and I fear some people believe it because they see it repeated in the papers. But from my knowledge

of bees, gathered in 25 years of practical work with them, I am led to conclude that some one is drawing on his imagination for his facts when such a statement is published.

I have never seen a pound of comb honey which I thought did not come from natural sources, and I have acted as judge at two international exhibitions, and at State fairs, besides inspecting honey in the markets for many years.

I fear that some retail grocers discredit comb honey put up in the best shape, for the purpose of working off the poor stuff they have on hand.

It is the opinion of all bee-keepers whom I know, that have experimented along this line, that bees will not touch glucose syrup unless compelled to by necessity, and then they would not be in proper condition to store surplus.

The colony must be in prime condition—prosperous, full of bees of all ages, and increasing in numbers before they will go outside the cluster to store honey. If there is not plenty of food available which they like, the condition above described will not be present, and, therefore, if they did have access to glucose syrup and nothing else, they would not be in condition to use it profitably.

Now, in defense of my argument, I wish to introduce the testimony of a couple of men who are bee-keepers. These statements were made before the National convention of bee-keepers last fall at Omaha, in answer to the question, "Is comb honey adulterated?"

Mr. Danzenbaker, who is a large bee-keeper near Washington, D. C., said:

"I don't think that bees will take glucose and put it into comb. Some years ago the Secretary of a glucose manufactory boarded with me. There were bees in the yard, and he took great interest in them. It was a hobby with him. In the early mornings he would be out there and have the hives open, and I found out that he was experimenting with glucose. He brought glucose and put it into the tops of the hives. I wondered what he was doing, and I found the glucose there. The bees would not take it. Then he took the best glucose sugar and put it in, and the bees wouldn't take it. It was during the honey season, and he thought the bees would mix with it the honey that was coming in from the field. He meant to keep bees. He imported a lot of Italian queens, and was thinking of making honey out of glucose, but the bees wouldn't touch it. I believe that the acid in the glucose would finally kill the bees. They have an instinct of sense that enables them to detect it."

Mr. George W. York, editor of the American Bee Journal, and President of the Association, added:

"I would like to give one instance of feeding glucose to bees that I know of. Mr. Grabbe, some years ago, was interested in bees with Mr. Perrine, in Chicago, who was one of the biggest adulterators in the State at that time. They moved two or three hundred colonies to Mississippi, and began feeding glucose, and it was scarcely any time at all until they had killed all their bees."

Now, if I have not occupied so much space as to rule me out of your columns, I hope you will give this reply the same publicity which the offending paragraph enjoyed. I might add, that the Association which I represent is using every possible means to bring to justice those who adulterate or contaminate the foods which we consume, especially honey; and we hope that the great State of Illinois will speedily pass such a pure food bill as will enable us to get after the adulterators of food products, whether they be bee-keepers or mixers in the cities.

Yours truly,
EUGENE SECOR.

We are again delighted. Mr. Secor answers the offending papers in such a complete way. It must do good in this instance, as in the case of the New York Evening Post several months ago. If we bee-keepers will just follow up this plan for awhile—of letting a little light on honey into the benighted heads of some newspaper correspondents and editors—it must result in overcoming, in a measure, the evil effects of the comb honey misrepresentation that was let loose on the public some 15 years ago. We believe the United States Bee-Keepers' Association is doing a great work when it keeps close after the offenders in question.

To take Grease Out of Cloth.—Make a mixture of the following parts by weight: Alcohol, 8; honey, 6; soft soap, 5; water, 5; wet the cloth with the mixture; rub lively; rinse in clear water. The mixture can be kept a long time if tightly closed in a bottle.—Mode Francaise.

"Queensound" is a word proposed by L. Kreutzinger to signify that a colony is all right as to having a good laying queen.—Gleanings.

MR. J. GORDON, of Dodge Co., Minn., writing us February 9, said:

"I get 'value received' in every copy of the Bee Journal. I could not get along without it and keep bees."

MR. W. BISHOP, of Otero Co., Colo., wrote us Feb. 4:

"It is cold, cold weather for Colorado. I suppose the bees think so, as snow has been on for a week, and storming most of the time."

MR. M. F. MAYER, of Green Co., Wis., wrote us Jan. 30:

"I like the American Bee Journal very much. I have had bees for several years, but could not produce honey to sell until I began reading the Journal. Long live the 'Old Reliable.'"

MR. R. C. AIKIN, of Larimer Co., Colo., President of the Colorado Bee-Keepers' Association, wrote us Feb. 7:

"This is awful weather; terribly cold. The past six mornings from 20 to 40 degrees below zero, averaging not less than 25 below each morning for the past week, and seldom much above zero during the day. We have had it below zero every day for about 10 days—I fear for bees—all outdoors in this country. Lots of snow here."

THE LEWISTON (ME.) JOURNAL is one of the leading eastern newspapers. In a recent issue it had this appreciated paragraph:

"The weekly American Bee Journal, of Chicago, enters upon the 39th year of its existence with the number for Jan. 5. It has well earned the sobriquet of the 'Old Reliable.' It is perhaps praise enough to say that Bro. York is the man to keep the Journal up to its previous high standard and abreast of the times in apicultural progress."

"HASTY SAYS GOOD-BY," is the ominous heading to an item in the Bee-Keepers' Review in which E. E. Hasty says he is compelled by the great amount of reading involved to close the series of "Views" he has been giving continuously in that paper for the past ten years. There must be something a little out of order in the mind of any reader of the Review who will not join with the editor in his regret at the necessity for such a step. Mr. Hasty has always had such an unfailing supply of good-nature, delicious humor, and upright and downright integrity, that the readers of the Review will sorely miss him.

DR. PEIRO, when on his visit to the Pacific Coast awhile ago, called on Mr. E. S. Lovesy, of Salt Lake City, Utah, President of the Utah Bee-Keepers' Association, and writes thus concerning him:

"I occasionally notice some practical, hard-headed facts regarding bees from the pen of Mr. Lovesy, which vividly reminds me of the delightful visit I had with him in Salt Lake City. I found him ensconced in his charmingly embowered home busy ministering to the comfort of his bees. He explained, among other thoughts of interest, that he was trying to circumvent the predatory instincts of the ants which greatly abound and as greatly annoy his colonies. Just how he has succeeded I am unable to state, but judging by the intelligent determination evinced, I suppose he has succeeded in his purpose.

"I much regret that my allotted stay in that beautiful city of saints did not permit me the pleasure of accepting his very kind hospitalities, but my gratitude to him and his good wife is none the less.

"Under the guidance of another friend I visited many of the noted places of interest there, even to taking a bath in the famous Salt Lake itself. This was one of the most singular and delightful experiences of my trip toward the setting sun. A very interesting chat with Elder Snow was exceedingly gratifying.

"Auf wieder sehen!"

DR. PEIRO.

Repairing (Bruised Comb Honey.—When a hole is punched in a nice section, E. A. Emmons makes a case-knife quite hot on a stove, then smears it over the hole, which covers it with a coating of wax. If the hole is very large, a bit of white comb from an unfinished section is dropt on. —Gleanings.

To Drive Bees Out of a Hollow Tree, put under the cluster a bunch of cotton-batting saturated in dilute carbolic acid. The odor is insupportable to the bees, and they will soon be clustered on the outside of the tree. If the entrance is above the cluster, bore a hole at the right place to get the carbolic acid below the cluster.—French Journal.

Queen-Excluders Hinder; according to evidence given in the Progressive Bee-Keeper, by F. L. Thompson. They restrict workers as well as queens, dead workers being found on top of the zinc, and a screen door composed partly of excluding zinc, altho it allowed bees to get out, did not admit robbers when robbing was rampant.

Carbolic Acid in Place of Smoke has been used much in England and Europe. A writer in L'Abeille et sa Culture says that bees conquered by the odor of the acid allow themselves to be handled or brushed without much resistance, and the odor of the honey being overpowered by the odor of the drug, the robbers are not troublesome, so the bees are less irritated and more tractable.

The Laying of a Young Queen.—The young queen always lays her first eggs without any order. She travels over the combs and lays at random. Upon a large comb I counted 13 sealed cells, and not more than three of them were together. The first eggs are generally found on the comb that contains the cell from which her young majesty issued, and it is only later, when the laying becomes abundant, that it becomes more regular. —Pfalzer Bienenzucht.

Foul-Broody Honey ; How long shall it be boiled?—In reply to a question some time ago in this Journal, Dr. Miller said that to make it safe to feed to bees honey taken from a colony infected with foul brood, the honey should be brought to a boil and held there not less than 2½ hours. Critic Taylor insisted 15 minutes was ample, and Editor Root endorsed the idea. The latter has changed his views, and has now become more radical than Dr. Miller, for he says, "I believe one will be taking risks if he feeds such honey if it has been boiled less than three hours."

Propolis is Often Mixt with Wax when it is used," says Editor Hutchinson. D. W. Heise showed him a cake of wax secured by repeated meltings from chips of propolis, altho it had a strong odor of propolis. Editor Hutchinson thinks we are losing a little wax when we throw away the scrapings of sections. Bee-Keeper's Review. —Why, haven't you often seen bees packing on their legs scrapings of wax found out-doors, and what else is done with such wax but to use it for propolis? And don't you know that the analysis of the lamented Dr. Planta showed more than half of ordinary bee-glue to be beeswax?

No-Bee-Way Sections are not viewed with favor by the editor of the Canadian Bee Journal. He thinks whatever advantage there may be in the open separator may be had with the old style of sections. Jacob Alpaugh makes fences with tin for the upright parts, and these are used with old-style sections. At the Toronto exhibition plain sections took no prizes. Sections of the ordinary kind shown there beat the sections shown by Danzenbaker at Buffalo. To the claim that plain sections will cost less for shipping-cases, he replies that different shipping-cases will cause confusion.

The Origin of Foul Brood is found in a fermenting mass of neglected dead animal matter and excretions, combined with the presence of a weakened colony, breeding and feeding amongst, and warming up to blood heat such neg-

lected matter, which they in a deteriorated state are unable to remove." This is the dictum of S. Simmins, editor of Bee-Chat. He disclaims any belief in spontaneous generation, but thinks the initial germ of foul brood is present in all healthy colonies, ready to grow whenever circumstances are propitious. He suggests that the primary seed is so infinitesimal that no scientist has so far discovered it. Inspector McEvoy is at least partly with him in his belief—a fact he mentions with apparent pride. Scientists who have produced the bacilli from the spores will hardly agree with the view that the primary seed of foul brood has not yet been discovered.

Bees and Fruit.—In Bienen-Vater are given results of some experiments in which netting was put over branches of trees at time of blooming. The time of blooming of blossoms on such covered limbs was prolonged as if the blossoms were waiting for the bees to fertilize them. On apple-trees the time of such blossoms was prolonged one to three days more than the time of blossoms uncovered. Pear-blossoms were prolonged four to five days; plum, four to seven days. No fruit set on the covered apple branches. Some fruit set on the other trees, most of it falling prematurely.

The Holtermann Hive-Cover is mentioned in Canadian Bee Journal by D. W. Heise, as a flat cover costing about the same as the ordinary cover, absolutely water-tight, and a good non-conductor of heat and cold. Something in that line has been needed a long time. (If I remember correctly our figures show that this hive-cover cost us more than the all-wood ones. It is cheap, as made by the E. L. Gould Co., because they have a good deal of sheet metal that is used for protecting certain packages, and this metal is practically good for nothing otherwise.—EDITOR.)—Gleanings. Whether it costs more or less, a water-tight, non-conducting cover will be likely to find a market.

The Braula Coeca, or Bee-Louse, is quite common across the water, and is sometimes found on bees freshly imported into this country, but somewhat curiously it never is reported as being perpetuated here. Probably not one bee-keeper in a thousand in this country has ever seen a bee-louse. H. W. Brice says of it in the British Bee Journal:

"What are its means of existence? Is it a scavenger or does it suck the juices of the bee? The latter is, I think, the more reasonable conclusion, but even where the Braula is found in large numbers bees seem but little inconvenienced by them, and they are usually more plentiful in strong colonies than in weak ones. They also have a decided preference for the bodies of queens, tho I have seen them scattered on all bees indiscriminately, tho the body of the mother-bee is, as a rule, the favorite haunt of the parasite. Why this is so I do not say, tho I think they have no choice, and if queens flew daily, as does the worker-bee, she would have just as few braulae as the rest."

The editor says it seldom lives more than one season in England.

Travel-Stain; what is it?—A thoughtful article from J. E. Crane appears in Gleanings, in which he resents the popular idea that the dirty feet of the bees traveling over the surplus combs are responsible for the darkening of the cappings. He says: "I consider the whole idea of travel-stain as a foul slander. The idea of our illustrious insects not being tidy is infamous." Sometimes bees carry pollen into the hives on their bodies, and this may have some effect in darkening the sections. Bees often use considerable propolis for capping late in the season when wax is scarce. But the chief source of the dark color on sections is the dark wax and old cappings carried from the brood-chamber into the super. One proof of this is that the dark color is not on the surface of the cappings, but the cappings are colored clear through. A queen is removed from a strong colony. All goes well so long as there is maturing brood to seal, but after eight or nine days the brood is all sealed, and yet the hatching bees are throwing off 1,000 to 1,500 cell-caps daily. Not being needed elsewhere, a good share of these cappings are carried into the super to darken the sections. The case is cited of a strong colony thrown on foundation in July, which remained queenless, and after four months the combs, even in the brood-chamber, were as white as the most fastidious dealer could desire.

The Premiums offered on page 62 are well worth working for. Look at them.

Root's Column

It seems to be generally admitted that a means for producing compression on sections when in the super is desirable, and some go so far as to say it is a necessity. If sections and separators are placed in supers loosely, it leaves little interstices or spaces that the bees fill up with propolis. Various devices have been used to bring about the desired compression. Some prefer and use thumb-screws; others, wedges; and still others, tightening-strips. Thumb-screws stick out in the way, and sometimes in damp weather become stuck fast in the holes. Wedges are very often propolized fast, making it difficult to remove them. The same objection applies to tightening-strips, altho to a less extent. We now use two or three springs to our 1899 supers, one at each end, bearing against the ends of the fences, and one in the center. See S in the cut below:

These springs produce a gentle, even pressure against the contents of the super; and, no matter how much the weather changes, causing the stuff to shrink or swell, those springs will produce always a gentle yet firm pressure. After the sections are filled they can be easily taken out, owing to the fact that there is a yielding pressure; and propolis—well, it has no show.

In the next Bee Journal we will show you how these springs are applied. Meantime—

KEEP YOUR EYE ON THIS COLUMN,

as it may save you dollars.

The A. I. Root Company
MEDINA, OHIO.

GENERAL ITEMS

Bees in Good Condition.

I have 30 colonies of bees, which were in good condition last fall. We had a poor year for bees here; I got only 50 pounds of honey per colony. We generally get 100 pounds per colony. I have kept bees for eight years. I started with two colonies. I have had the Bee Journal two years, and am going to continue taking it. Two days ago the bees had a flight, and today it is 10 degrees below zero. GEORGE WEIS.
Washington Co., Ohio, Dec. 31.

Bee-Keeping for Recreation.

I have taken the Bee Journal but six months, but permit me to say I am much pleased with it. I consider it valuable to anyone keeping bees either for pleasure or profit. My business is merchandising, and I keep bees simply for amusement, and I assure you there is nothing that will drive care from a man's mind, or afford more pleasant, healthy amusement, than a few colonies of well-bred Italians. I have kept bees two years; last spring I had one colony and a poor excuse for another. Nov. 1 I put seven good, strong colonies into winter quarters. R. DAVIS.
Charlevoix Co., Mich., Dec. 30.

Wintering All Right So Far.

Bees here are going through the winter so far in good shape; they had a fair flight yesterday, and are cooled off this morning by a cool breeze with the thermometer 15 degrees above zero. A. A. HOUSER.
McDonough Co., Ill., Dec. 30.

Bees Had a Flight.

Bees are flying today at 44 degrees above zero, and are packed all around with wheat chaff. How is that for not warming up through the packing? I believe the warmth gets in through the entrance. Long live the American Bee Journal!

MICHAEL HAAS.
St. Joseph Co., Mich., Dec. 29.

Have Plenty of Stores.

Most of my bees have plenty of stores for winter, but they produced no surplus worth talking about, and that was of very dark color. One of my colonies stored 70 pounds, and another 80 pounds of surplus. These colonies were right among the rest that seemed quite as strong as they were. GEORGE SAGE.
Greene Co., Ind., Dec. 31.

Crop Almost a Failure.

The honey crop here the past season was almost a failure. I secured about 500 pounds from 21 colonies, against 1,600 the year before, from the same number of colonies. CHAS. W. CONKLIN.
Logan Co., Ill., Jan. 3.

Selling Honey—Competition.

Altho failure is reported all around, yet I succeeded in obtaining from 22 colonies, spring count, over 1,000 pounds of extracted honey—all clover and basswood; and also did away with swarming. As I could give but one day out of the week to my bees all through the season, and then had to come 12 miles to see to them, I think I did fairly well. I am at present testing a new plan for selling honey, which I believe is going to be ahead of anything I have ever read on the subject (and I have read all in the Bee Journal for 2½ years), for those who are

SWEET CLOVER

And Several Other Clover Seeds.

We have made arrangements so that we can furnish Seed of several of the Clovers by freight or express, at the following prices, cash with the order:

| | 5lb | 10lb | 25lb | 50lb |
|---------------------------|-----|--------|--------|--------|
| Sweet Clover melilot..... | 60c | \$1.00 | \$2.25 | \$4.00 |
| Alsike Clover..... | 70c | 1.25 | 3.00 | 5.75 |
| White Clover..... | 80c | 1.40 | 3.00 | 5.00 |
| Alfalfa Clover..... | 60c | 1.00 | 2.25 | 4.00 |
| Crimson Clover..... | 55c | .90 | 2.00 | 3.50 |

Prices subject to market changes.

Add 25 cents to your order, for cartage, if wanted by freight.
Your orders are solicited.

not born agents; and I believe it is also a good plan for them. So far it has been a success, and is so simple I wonder others have not thought of it. After I prove its success or failure I will report through the Bee Journal.

I am trying this plan in the city of Flint, where honey can be found in the stores at all seasons of the year.

At present I have 35 colonies in winter quarters, in good shape.

As I have Editor Hutchinson, his "neighbor Koeppen" with his 370 colonies, and a Mr. Torrey with about 100 colonies, on the west side of me; Hon. R. L. Taylor, with his large apiary, and Rufus Ivory with 76 colonies on the east, and Jones Skinner with about 75, and a man named Doane, with over 200 colonies, on the north, besides numerous small apiaries around me, you see there is plenty of competition.

E. B. TYRRELL,
Genesee Co., Mich., Dec. 19.

Congratulations - Cleansing Flight.

EDITOR YORK:—I offer my congratulations for the success you have achieved as a publisher of so valuable a journal of knowledge and information for the bee-keeping fraternity throughout the world. I hope you will be handsomely remunerated for your labors, and that you may, with the help of its contributors, make the American Bee Journal a mirror in which its readers can see and understand the mysteries of bee-keeping more clearly in the future than they have in the past.

Bees here had a cleansing flight Dec. 23, with no snow on the ground.

White Co., Ind. A. WORTMAN

Credits the Bee Journal for Success.

The American Bee Journal has worked wonders with me in teaching about handling my bees, which did well last season. I took from one hive 110 pounds of honey, half extracted and half comb. I look at them last Monday, and they are wintering in fine shape. I owe all my success to the American Bee Journal, as I knew nothing about bees until I commenced to take it.

JOHN A. FLETT,
Hennepin Co., Minn., Dec. 30.

Wintering Well.

My bees had a nice flight to-day, and they are wintering well so far. I have 17 colonies.

THEODORE SIMPSON,
Greene Co., Pa., Dec. 28.

Got No Honey in 1898.

We got but a few pounds of honey the past season. We like the American Bee Journal very much; it has been a great help to us, and tho we got no honey the past two seasons we may profit by what we have learned, in the coming season.

F. C. McCLAIN,
Mason Co., Mich., Dec. 30.

Giving Bees Winter Flights, Etc.

Dec. 29 was a warm, springlike day. Seeing that some bees were flying a little I exposed all the fronts of the hives that I could to the morning sun, and aroused the rest by drumming on their chaff hives and boxes. By noon they were flying freely, and carrying out dead bees. Up to this date my bees had no flight for about six weeks. Now I feel much relieved as to their wintering.

Last winter my bees had no flight for 3½ months, and then I had to take them out of their chaff hives and boxes, and set them on snowdrifts in order to give them a flight. I think bees should fly once a month, and when my bees are compelled to stay in three or four months, I feel quite uneasy. (I mean when packed in chaff hives, or any out door wintering.)

Many colonies were scant in stores last fall, and no doubt hundreds of colonies will

perish in this county alone. Some people, seeing that their bees were scarce in stores killed them. It seems to me that the shortage of bees will be felt as much next year as a short crop of honey was felt this year, and tho a good season may come the honey crop will be short still.

This one thing I have learnt this year: By taking the Bee Journal I could keep trace of the markets and knew how to sell my honey. Some men who take no newspaper sold their honey for from 10 to 15 cents. I sold mine at from 11 to 15 cents early in the fall, and if I had more I could sell it for 20 cents now.

Through the Journal I also learned to drum out the bees when it is entirely safe for bees to come out. I like the Bee Journal very much, and do not see why some do not want it. Success to the American Bee Journal. D. J. BLOCHER. Stephenson Co., Ill., Dec. 31.

Bees Didn't Do Well.

I am in the bee-business in a small way. I commenced last spring and got 21 colonies together, and have now 15. Bees did not do very well here last season. I don't think this is a good location for bees. Mine were almost all new swarms, so I didn't expect much from them, but I expect to continue in the business. M. E. BUCK. Washington Co., Oreg., Dec. 27.

Bees and a Sorghum Mill.

I keep about 80 colonies of bees and get a fair crop of honey every year. I run a sorghum mill about six weeks every fall. The mill is located 15 rods from the bees. The first three weeks the mill is in operation the bees try their best to get at the sap, but I keep a good smoke under the press, and if the smoke is started before the bees start stealing they won't trouble much. If I were not the owner of the mill, and tended to the smoke it would not be safe for man or beast to be near the press. Besides, the bees would store sap in sufficient quantity to give them the diarrhea before the New Year, and I believe it would take only one season for the mill to kill the bees. But the two industries have worked well together for the last 12 years. I have so far not lost more in wintering than others whose bees have no access to sorghum sap. ANDREW CARLSON. Chisago Co., Minn., Jan. 18.

Wintering Well in the Cellar.

I am wintering 120 colonies of bees this winter, in a cellar 12x40 feet, about 7 feet high. I have wintered them thus for a great many years. I have been living here for about 40 years, and have kept bees about 36 years. My bees are wintering well. WILLIAM FLEMING. St. Croix Co., Wis., Jan. 25.

Wintering Nicely—Cold Weather.

Bees are wintering nicely this year with me; very few dead ones. It has been 26 degrees below zero. I see some claim they could not get along without the Bee Journal. Well, I could, but am not going to as long as I keep bees and can get the dollar. JOHN MICHAELS. Clearfield Co., Pa., Jan. 20.

Stingless Bees in Old Mexico.

I was very much interested in Prof. Bruner's address at the Omaha convention, about stingless bees, as I have two colonies of them in my apiary. They are very different from the ordinary bees as they are about 3-16 of an inch long and are black, except the queen, which is yellow, and twice the size of the workers. They work in hollow trees and accumulate quite a quantity of honey—sometimes three or four pails of honey can be gotten out of a hive. The honey has an acid taste, and is very palatable—in fact, a person can eat more of it than of the ordinary honey as it

has not the sickly taste. The wax is very dark-colored and is used for medicinal purposes. The comb in which the honey is stored is quite a curiosity, as it consists of balls about half an inch in diameter, which are fixed on a stem; then to this they keep fixing other balls, till they make one mass of comb, and in and between fix the brood-comb, which is similar in shape but smaller than the ordinary bee-comb.

My bees are gathering honey from peach blossoms, and seldom miss a day going out, so I am not very much interested in the discussion on wintering bees.

I have also a colony of bees that are between the big or ordinary and the small or stingless bees, but these build in the branches of any tree, and the comb is just like papier-mache, and the honey very sweet.

My hive is 18 inches in diameter.

SAMUEL ANDREW.

Nuevo Leon, Mexico, Dec. 25.

Report from South Alabama.

I thought it would not be amiss to let the bee-keepers in more Northern latitudes know what our bees are doing down South. The winter caught me with 24 hives weak in bees and stores, caused from too much rain in late summer and fall; also from dividing for increase. I am now (Jan. 15) feeding out-doors. I prefer it for several reasons, and none more than to hear that joyful hum in the hive morning and night. They are also carrying a good deal of pollen in. I cannot tell from what source they get it. There is some peach bloom at the present time.

We have a fine climate for bees, but we never have an abundant flow of honey, from tree or plant, as the papers speak of coming from those farther north. By the middle of June our whitest and largest flow is over. We have a good deal longer time to rear queens in, altho I have not tried it yet.

SOUTH ALABAMA.

Washington Co., Ala.

An Experience with Bees.

I think it was in 1889 I took the bee-fever, and it came near flooring me. I purchased four colonies of bees in box-hives, and moved them home done up in horse-blankets. They made no trouble, as the weather was so cold that it was sure death to a bee to even poke her nose out. I think it was in February. I believe the "Sage of Marengo" would rather move them in warm weather, but say, Doctor, they are not nearly so liable to sting in cold weather!

I packed the bees in chaff, and procured a dozen chaff hives.

When spring came I transferred the combs and bees into the Langstroth frames. In due time they swarmed, as any well-behaved bees should do, and in two or three years the hives were full; and I would get 300 or 400 pounds of honey every season.

But last spring I decided to get some more hives, and also straighten up what I had, and try to follow orthodox methods. So I got everything ready early in the spring, and knowing that those old hives and frames were in a horrible shape, I transferred the best of the combs and melted up the balance. Some of them were built on starters, and I guess some were started on empty air. Some sheets were tolerably good, and some were every cell drone comb; but I got through with the job, and after the old combs were patched up by the bees and the full sheets of foundation were drawn out, and every cell worked, I felt proud of them. I honestly believe the old veterans couldn't beat the job themselves.

But just about the time the combs in the brood-chamber were filled it came on wet, wetter, wettest, and our surplus was small. About this time, having previously purchased an Italian queen, I decided to try my hand at requeening; so I hunted up all the authority I could find and sailed in, and at the first pop I got 18 nice cells in a row (1

MAKE MONEY OUT OF POULTRY.

BEST

EXTRACTED HONEY FOR SALE.

ALL IN 60-POUND TIN CANS.

ALFALFA HONEY.

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

BASSWOOD HONEY.

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms in Wisconsin. It has a stronger flavor than Alfalfa, and is greatly preferred by those who like a distinct flavor in their honey.

Prices of either Alfalfa or Basswood Honey:

A sample of either, by mail, 8 cents; samples of both, 15 cents—to pay for package and postage. By freight one 60-pound can, 8 cents a pound; two cans, 7 1/2 cents per pound; four or more cans, 7 1/2 cents per pound. Cash must accompany each order. If ordering two or more cans you can have half of each kind of honey, if you so desire. This is all.

ABSOLUTELY PURE BEES' HONEY,

The finest of their kinds produced in this country.

We would suggest that those bee-keepers who did not produce any honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere. "YORK'S HONEY ALMANAC" will be a great help in creating customers for honey. See prices on another page.

mean a rainbow), as per Alley. So now I have 18 good colonies in winter quarters, each with a good queen, either pure Italian or hybrid, as I had excellent luck in getting those cells hatch and queens laying.

One thing in regard to the above I must give you from my record book: Hive No. 19—July 23 I gave unfertile queen; Aug. 2, no eggs; I gave Italian brood, whole frame; Aug. 9, saw queen but no eggs, and gave Italian larvæ as per Alley; Aug. 19 I found full of brood, some brood in several more combs, and four nice queen-cells. Question—Why didn't she go to laying at 8 or 10 days of age, instead of waiting until she was at least 26 days old? L. L. TRAVIS. Wyoming Co., Pa.

Poor Season—Cellar Wintering.

We had a very poor season for honey in 1898. The worms destroyed most of the basswood blossoms.

Tell "Iowa Joe," who spoke of cellar wintering with bottomless hives (page 695, 1898) that I place a four-inch super under the hive in place of the bottom board, with wire-screen on the bottom side, which keeps the mice from getting in, and the bees from getting out. The dead bees drop down on the screen. My bees winter nicely that way. Leave them thus until you put the bees out on the summer stands, and there will be no loss of bees flying out in the cellar. E. B. LANGDON. Douglas Co., Minn., Jan. 17.

An Illinoisan in Arkansas.

My honey crop for 1898 was very good for the first year in Arkansas. The spring was very wet and almost all summer, but in the fall we had about 8 or 10 days when the bees and myself put in overtime, as golden-rod and Spanish-needle yielded a heavy flow of nectar, and after 8 or 10 days we got a heavy rain; then it was over for 1898.

I started in the spring with 45 colonies and increased to 100, having bived back about 40 swarms, and about 10 swarms took the traveling fever like a good many Arkansas people do, and left me because I was not able to hive them. I got about 3,000 pounds of nice honey and 100 pounds of wax. I always made my living from bees, and there are eight in my family. I have the American Bee Journal and the Italian bees. Let me have the "Old Reliable," and I am all right. F. J. GUNZEL. Craighead Co., Ark., Jan. 17.

The Midland Farmer SEMI MONTHLY.

BUY THE BEST.

If you want the best low down wagon you should buy the Electric Handy Wagon. It is the best because it is made of the best material; the best broad tired Electric Wheels; best seasoned white hickory axles; all other wood parts of the best seasoned white oak. The front and rear hubs are made from the best angle steel.

which is neater, stronger, and in every way better than wood. Well painted in red and varnished. Extra length of reach, and extra long standards supplied without additional cost when requested. This wagon is guaranteed to carry 4,000 pounds anywhere. Write the Electric Wheel Co., Box 16, Quincy, Illinois, for their new catalog, which fully describes this wagon, their famous Electric Wheels and Electric Feed Cookers.

WANTED AN APIARIST.

A competent man can secure a position for the coming season by communicating with the office of the American Bee Journal. 6A4t

HONEY AND BEESWAX MARKET QUOTATIONS.

CHICAGO, Feb. 9.—The trade is not active in comb honey, many of the retail dealers being supplied with sufficient stock to meet demands for some time to come. Prices are quite steady with 13c for best white, off in color, etc., including amber grades, 10c-12c; dark, 9c. Extracted 6c-7c for white; amber and dark, 5c-6c. Beeswax, 27. R. A. BURNETT & CO.

DETROIT, Jan. 2.—No change in supply of honey as to quality, but prices are somewhat lower than last quotations, viz: Fancy white, 13c; No. 1, 12c-12.5c; fancy dark and amber, 9c-11c. Extracted, white, 6c-7c; dark, 5c-5.5c. Beeswax, 25c-26c. M. H. HUNT.

INDIANAPOLIS, Jan. 4.—Fancy white comb, 12c-12.5c; No. 1, 10c-11c. Demand fairly good, Dark comb honey is being offered at 8c-9c with almost no demand. Clover and basswood extracted, 6.5c-7c. Beeswax, 26c-28c. WALTER S. POWDER.

NEW YORK, Jan. 20.—Fancy white, 12c; No. 1 white, 10c-11c; amber, 9c; buckwheat and dark, 7c. Extracted in good demand at unchanged prices. Beeswax rather quiet 27c-28.

Trade in comb honey is quiet. White is pretty well cleaned up, but there is a large stock of buckwheat, amber and mixt, having accumulated of late, and in order to sell in quantity lots it is necessary to shade quotations. HILDRETH BROS. & SEGELKEN.

SAN FRANCISCO, Feb. 1.—White comb, 9.5c-10.5c; amber, 7.5c-9c. Extracted, white, 7c-7.5c; light amber, 6.5c-6.5c. Beeswax, 24c-27c.

Stocks of all descriptions are light and are largely in the hands of jobbers. At current values, however, not much is required to satisfy the demand. Supplies of Water White Extracted, uncandied, are practically exhausted.

BOSTON, Feb. 8.—The demand for comb honey is very light, with full stock on hand. We quote our market: Fancy white, 13c-14c; A No. 1, 12c; No. 1, 11c-12c; light amber, 9c-10c. No demand for buckwheat. Extracted, white Northern stock, 7c-8c. Beeswax quiet at 27c-28c. BLAKE, SCOTT & LEE.

KANSAS CITY, Jan. 25. Fancy white comb, 13c; No. 1, 12c; amber, 11c; dark, 10c. Extracted white, 6c; amber, 5c; dark, 4.5c. Beeswax, 25c. C. C. CLEMONS & Co.,]

BUFFALO, Jan. 27.—There is a little more activity on strictly fancy 1-lb. combs at 12c. The bulk of receipts of low grades sell at 10c. down to 7c, and in a few cases even less. A moderate amount can be sold every day. Extracted, 4c-6c., according to quality. BATTERSON & Co.

CLEVELAND, Jan. 2.—Fancy white, 13c-14c; No. 1 white, 12c-13c; A No. 1 amber, 10c-11c; No. 2 amber, 9c-10c; buckwheat, 8c. Extracted, white, 7c; amber, 6c; buckwheat, 5c. A. B. WILLIAMS & Co.

MILWAUKEE, Jan. 9.—Fancy 1-lb. sections, 12.5c-14c; A No. 1, 12c-12.5c; No. 1, 11c-12c; dark or amber, 8c-11c. Extracted, in barrels, kegs and pails, 6.5c-7.5c; dark, 5c-5.5c. Beeswax, 25c-27c.

The condition of the market is favorable for shipments of honey, especially of best grades, which are in small supply. The sales are moderate, but we are expecting an increased demand and good trade this spring. A. V. BISHOP & Co.

MELILOT OR SWEET CLOVER.

How to Sow It and Grow It for Hay and Honey.

BY WM. STOLLEY.

I NOTICE that quite frequently Dr. Miller is still bombarded with questions regarding sweet clover, such as, preparing the ground for the planting of its seed, how to plant, how to make hay of it, when to cut it, etc. Now, if the Doctor will not consider it trespassing on his domain, I will touch upon some of these questions for the benefit of beginners, and tell them what I know about sweet clover from experience.

Those contemplating the growing of melilot (sweet clover) as a field crop, may very properly take for it any small-grain-field stubble, or a corn-field, sowing the seed broadcast, and using from 15 to 20 pounds of seed to the acre, without any further preparation of the soil whatsoever, except harrowing the rather compact soil with a sharp-toothed harrow after sowing.

The sowing may be done at all times after the ripe seed begins to drop to the ground, and from that time on clear into, and during winter, but it should not be done too late in the spring, for fear that a dry spell may injure or destroy the young, tender plant before it has sent its taproot deep enough into the moist soil below.

Of course, seed sown on frozen land cannot be harrowed and thus slightly covered; but this is hardly needed. The tramping into the soil by stock, and the action of melting snow, is all that is required for the seed, if good, to sprout and take root early in the season, having the benefit of all the winter and early spring moisture. In fact, melilot seed sown on country roads, and alongside of railroad tracts, or vacant places, if the seed be good, always gave good results with me. I have tried it, and hereby acknowledge that I am guilty, even if it should be considered a crime.

Those growing melilot as a field crop generally expect to derive other benefits besides a reliable honey crop, viz.: such as pasture for stock, cropping it for hay, or enriching poor and worn-out land. Melilot will do all this, and even more. Melilot is a good and efficient subsoiler.

If a good stand is secured in its first year's growth, it should be cut for hay about the first of July, depending somewhat on the headway it has made by that time; the next cutting may be done about six weeks later on; but do not cut too close to the ground, lest you may risk killing the plants. Leave a stubble of from 3 to 4 inches high, and the plants will not be injured.

Melilot being exceedingly succulent, requires much longer curing than any other plant utilized for the making of hay. It should remain on the field, as cut, without work-

ing or turning it until it is ready to be housed or stacked outside, so as not to lose a large percentage of its leaves, which, when dry, are very brittle, and easily drop off.

It is best, in loading on a wagon, to use a hayloader attach to the wagon. Thus in 10 or 15 minutes the wagon is loaded, and but one good man is required on the wagon to do the work.

The unloading is also best done with a grabblefork, or, still better, with a so-called "sling." It is very hard work to do the unloading with a common pitchfork.

While housing or stacking a liberal sprinkle of salt should be given on each layer as it is spread out. This will improve the quality of the hay, will tend greatly to prevent heating, and is greatly relished by the stock feeding upon it.

Melilot must remain in the field to cure at least double the length of time that alfalfa requires, and therefore will bleach considerable; but this bleaching does not in the

Wm. Stolley.

least injure the quality of the hay. It should be worked, when secured, only early in the forenoon and towards evening to prevent loss by waste of dropping leaves.

In the second year of its growth, if hay as well as bee-pasture is the object in view, melilot should be cut not later than June 15, with a stubble from 4 to 5 inches high, and

after that it should be allowed to mature seed. Thus treated here in Nebraska, it will furnish most excellent bee-pasture up to the time when frost kills all vegetation, and sweet clover is the very last to succumb.

For early spring pasturing of cattle, particularly milch cows, there is nothing better than sweet clover. I never knew it to bloat them, altho my cattle have pastured on it year after year from morning to night, when no other plant food was in sight, and while it was wet with dew and rain. Pasturing cattle on alfalfa in the same way would frequently have been with fatal results.

While sweet clover is in no way objectionable on cultivated fields and pastured lands, it is objectionable whenever it gets a foothold on original prairie-grass land which is to be utilized as hay land. By the time that our native prairie-grass is ready for the mower, sweet clover is gone into seed, the stems have become as hard as wood, and thousands of seeds have dropt, thus spreading gradually all over the grass field. Raking together the hay tends still more to scatter the seed broadcast over the infested land, and eventually sweet clover is sure to run out "old America." But, then, the best of us are not free from sin, and why should sweet clover be!

On public highways it is the best plant to grow, if only properly treated. It runs out all noxious weeds, perfumes the air, and feeds the bees; and to the eye of the bee-keeper it looks very nice, even if it should grow 10 feet high.

If cut about the middle or towards the end of June, leaving a rather high stubble, it is dwarfed sufficiently in its growth to prevent its becoming a nuisance by growing so high as to cause snowdrifts in winter.

Should a too luxuriant aftergrowth follow the first cutting in June, the mower has easy work to lay everything flat late in the fall. That is the way I deal with this useful plant.

A public road, well and evenly seeded down with melilot, but the growth of it properly checked at the proper time, is a thing of great beauty, and there is nothing bad about it, but, instead, it furnishes a bee-ranch hard to beat, because it will employ the bees until killing frost ends the season.

I am advised that a very extensive sheepman about ten miles north of my farm has seeded down a very large tract of land with sweet clover for a sheep pasture. Very few sensible men, indeed, will nowadays say that cattle, horses or hogs will eat the "blamed stuff," for it has been proven too often that *all of them* will.

I very well remember the time—some 35 to 40 years ago—when this country was still full of Indians, that their ponies would not eat our corn. Well, these animals soon learned to like it much quicker than some men will learn that sweet clover is a good thing, and that there is no serious objectionable feature about it, provided it is handled as it should be handled.

Now, Mr. Editor, I am bitterly opposed to all kinds of monopolies, and therefore I consider it time for me to stop my pencil right here on this subject, so as not to monopolize too much space in your highly-valued paper. I have preserved every number of all the volumes of the American Bee Journal for over 18 years, which fact I think proves best my appreciation of the "Old Reliable." May it ever flourish.

Besides some other topics, I will probably have something more to say about sweet clover later on, if agreeable.

REPORT FOR THE SEASON OF 1898.

It appears that the season of 1898 was not a very propitious one for a great number of bee-keepers. I notice in glancing over the many reports in the American Bee Journal, that many of those who have sent a fair or good report attribute their success principally to sweet clover. So it is with me. Sweet clover as a reliable honey-yielder is "the queen," at least here in Nebraska.

I began the season of 1898, in May, with 22 colonies which I worked for extracted honey, and 5 colonies in the Heddon hive for comb honey, after I had sold about \$80 worth of bees.

I obtained 2,890 pounds of extracted honey, and 375 well-capt 4½ x 4½ sections of comb honey—a total of 3,265 pounds. I increased from 22 colonies to 30, and from the 5 Heddons to but 6 colonies, so I am wintering 36 colonies.

Besides the above, I set aside for spring and June feeding 157 brood-combs, containing at least 550 pounds more of sealed stores, while each colony had not less than 25 pounds of honey to winter on.

I winter my bees in an open shed, on the summer stands, in double-walled hives, all packed inside the hives. The bees in the Heddon hives are, summer and winter, in a

suitable vault, which in winter is filled with dry soft-maple leaves. In 18 winters I have never had trouble in wintering my bees.

I obtained a little over 30 pounds of the finest wax from the cappings rendered in a solar wax-extractor of my own make.

The foregoing is my report for the season of 1898. Now, if I had not had sweet clover growing all around me, what would my honey crop have been? Indeed, very little if any at all. One-half of my last year's crop, I may say, was pure melilot, or sweet clover honey, and my fall crop of darker-colored honey is intermixt with melilot and alfalfa so as to consist of about three-fourths of it, while about one-fourth is derived from wild fall bloom, making it of amber color and pleasant taste.

Hall Co., Nebr., Jan. 30.

Something About Queens and Queen-Rearing.

BY DR. E. GALLUP.

AS I promise to give something of my ideas about queens and queen-rearing at the time that I got up the large hives, here goes.

The reader will recollect what I have said about seeing extra-long lived and prolific queens in large hollow logs in a small house built purposely for bees, in extra-large boxes, etc. In consequence of this I had extra-large ideas, and in some way I have never yet seen any reason for changing those wild fancies, as some have seen fit to call them.

Where bees take their own time and supersede a queen at the right season, and in a strong colony, I have invariably had good queens. I removed a queen from one of those strong colonies right in the season, when it was good weather or swarming time, removed all unsealed larvae, left the sealed brood and only eggs, introduced two frames of eggs from other queens, so I had three frames of eggs in different parts of the hive separated from each other. Now understand I had a large working-force of outside or field bees, and a large force of inside working bees or nurses, yet I went to different colonies in the middle of the day and took out frames of comb with the adhering nurses and shook them down in front of my prepared colony, from several different colonies, until I had a hive running over full of nurses, as the nurses, having never had a flight, staid where they were put, of course the old bees went back. By allowing them none but eggs to start queens from, I did not run any risk of having queens started from larvae too far advanced as we many times do.

Well, the result was, I had 36 extra-large cells built, and saved 30 of the first lot of queens, and every one turned out as satisfactory a lot of queens as I ever had. I was not expecting so large a number, consequently I was not prepared to take care of them all. You can readily see that having so many nurses and strangers, as it were, from many different colonies, they built large cells, and after the queens hatched out there was left in each cell a quantity of royal jelly nearly if not quite as large as a common marrowfat pea. So they were reared under the very best possible conditions. That was experiment No. 1.

After removing the first lot of cells and queens I filled up again to overflowing with nurses as before. The weather was still excellent. This time I gave four frames containing eggs, separated from each other in different parts of the hive; no division-board was used, and I had 38 cells built. I lost some of this lot in getting them fertilized, as the weather turned bad. What I did save turned out perfectly satisfactory. I then quit the bees and went into my present occupation.

I tried the experiment again in Ventura county, with a 3-story 10-frame Langstroth hive, and reared 30 good extra ones the first experiment.

I need not tell you that I am in favor of extra-large hives and powerful colonies, both where I lived in Iowa and here in California, either for honey or queen-rearing.

Orange Co., Calif.

Some of the Insect Pests of Cuba.

BY O. O. POPPLETON.

ON page 820 (1898), Mr. Danzenbaker asks me for information about the drawbacks of a life in Cuba, especially the insects found there. This is a rather peculiar subject to find a place in bee-literature, nor will it make the pleasantest of reading, yet it is important that one who

moves into a southern country, should know beforehand something about the annoyances he is sure to meet, and how best to lessen them as much as possible.

There are mosquitoes in Cuba, plenty of them, but they are neither so many nor of so mean a disposition as those we have here on the East Coast of Florida. There are said to be a dozen different species of them in Cuba, but those I got acquainted with were the shyest and most cowardly fellows of their kind I know anything of. They never bothered at all in the daytime, not even in the thickest of brush or in creek bottoms. Always in the evening, when sitting on the piazza, there would be a swarm of them back of us, but rarely indeed would one of them venture to alight on us long enough to bite. The least motion of any part of our person would cause them to dart away to a safe distance. The time when they trouble is after we get to bed, and they can trouble little or none then if one has a good, tight house, or uses mosquito nets over beds. Doors and windows of the houses must be kept screened, or nets used over beds the year round, and care must be taken that no mosquito is inside of the net, after one gets into bed. All such must be killed before trying to sleep.

I was told that the ordinary kind of mosquitoes was very bad at times, close to the ocean, say within half a mile or so of the shore, but, taken all in all, mosquitoes were less of a pest in Cuba than in any other part of the South I have ever lived.

By far the worst pest we found was fleas—the common, old-fashioned, high-jumping fellows. We found it impossible to prevent serious annoyance from these, that is, in the daytime; but we could keep quite free from them at night by not allowing our night-clothing to come into any contact with clothing worn in the daytime; and the more we kept away from any place where any kind of animals was kept, the less we were troubled with them. I am told they can be kept away by the free use of insect powder. If I were going to Cuba I should take a supply along with me.

A pest not found so far as I know in the States, is the Chigoe—the *Negaa* of the Cubans. This is a flea, a jumper, black, and so small as to be almost invisible with the naked eye. These fellows burrow just under the skin, usually at the side of one of the toe-nails (big toe preferred), and then proceed to grow into a bag full of eggs. I think that the abdomen of the insect itself distends as the eggs grow in size. I have seen them the size of a kernel of wheat. The first one knows of their presence is a peculiar itching, and an examination will show what looks like a white fester under the skin. A novice will open the supposed fester, squeeze out the eggs, and if wise drop in some kerosene to kill the insect and such eggs as will still remain.

But that is not the thing to do. The egg-sac remaining in the flesh will act like any other foreign body, causing inflammation and suppuration, and a good deal of pain and soreness for a few days. The right thing to do is to take a pin, and by being very careful, separate the entire egg-sac, *without breaking it*, from the flesh. This is not a sore or painful operation to do, but requires slow, careful work, and, if rightly done, leaves no bad effects except a bothersome itching for a day or two. I had only four of these fellows to wrestle with during the two years I was in Cuba, and my wife had two; but the natives, who went nearly or quite barefoot, were troubled very much, especially those who had much to do around where stock was kept.

There are a great many scorpions there—more and very much larger than we have here in Florida. Empty hives are favorite places for them. It was of daily occurrence to kill one or more, but it is rare to be stung by them. I have been stung only once while in Cuba, and once here in Florida. The sting is a little more severe than is a bee-sting, but not much. I think the scorpions found in America are much less venomous than are the Asiatic and African species.

There are said to be no venomous snakes in Cuba, and not many of any kind. Guess St. Patrick must have made a brief visit to the island some time or other, as almost all other tropical countries are infested with poisonous serpents.

I neither saw nor heard anything of either sandflies or bedbugs while in Cuba. These last are found in several of our own Southern States, and are a genuine nuisance, indeed, altho they use few persons as badly as they seem to have done Mr. Dauenbaker. The remedy he gives for them is probably good, but not so readily applied as one we use. It is simply to anoint the lumps caused by them as soon as one feels them, with a preparation called "The Magic Mosquito Bite Cure and Insect Exterminator." This preparation has no offensive odor, and seems to both kill

the insects and allay the itching and discomfort caused by their bite; and is much the best remedy I have ever found for any kind of insect bites. It is quite cheap, costing 20 cents per pint, or \$1.00 per gallon. It is claimed to be a perfect destroyer of certain insects that sometimes infest houses, but I cannot say as to that from actual use.

Mr. D. misunderstood what I said about foul brood in Cuba. I said, "There was none while I was there;" but I learn through the papers there has been some there since then. I try, as a rule, to write only what has come under my own observation, leaving others to tell what they have seen.

Dade Co., Fla.

COMB HONEY VS. EXTRACTED.

Those Proposed Experiments for Comparative Yields.

BY R. C. AIKIN.

IN the preceding article (see page 67) I treated of a plan to secure a comparative test to find the difference in yield between comb and extracted honey, conditions equal save that the comb-honey colony builds its comb while that for extracted to have combs ready-made. I now continue the discussion.

The experimenter having followed my plan of management up to the harvest, should have every colony very nearly equal in bees, age of bees, and amount of brood in all stages. Having attained this, and the honey-flow on, I recommend to unqueen where the flow is confined to one short season, and so control all swarming (for unqueening method see a later article), and if two flows, or a very long one, to cause all to swarm at same time.

As to management when they do swarm, if all swarm it matters but little what method is pursued so long as all are treated alike. I think, however, that more accurate results will be obtained if the working force be kept together, say by hiving on the old stand and setting the old colony somewhere near to be later removed to a new location, thus adding to the swarm all bees that can possibly be spared from the old one, expecting nothing more of the old one but to fill the brood-chamber and be ready for winter.

As to whether they be hived on starters, full sheets of foundation, or fully built combs in the brood-chamber, I should prefer first full sheets, and, second, starters. It will be necessary to use queen-excluding honey-boards, especially on the extracted-honey colony when full combs are above and starters of foundation below, else the brood-nest would be established in the extracting-combs. It would be unwise to put ready-made extracting-combs on at the same time a swarm is hived on starters or foundation, because the bees would so largely take to the extracting-combs as possibly to refuse to build in the brood-chamber. First let the swarm get started in the brood-chamber, and, started there, put on the extracting-combs. The extra may be put on at once if zinc is used and combs below.

Let no colony suffer for room. Weigh off the surplus from each hive, and keep the amount in the colony record. When the flow is over, and all surplus off, weigh each hive to determine the amount of honey in the brood-chambers. Do not forget to find out the amount of honey in the *brood-combs*. It is almost an invariable rule, that more honey is stored in brood-combs of section-honey colonies than in those run for extracted. The rapidity (freeness) of the flow and strength of the colony have to do with this, and it is no uncommon thing for a section-honey colony to have its brood-combs *packed* almost full of honey, and very little brood, and along side of it an extracted-honey colony having *very much brood*, and what honey-combs are in the brood-chamber not well filled. Brethren, thereby hangs a tale—so be sure to find out how much honey is in the brood-chambers.

OTHER EXPERIMENTS.

There is another way to accomplish something definite, and by a method that requires few bees, and less time, but requires bees from one location to another. Here is how I expect to work it:

I shall make a box largely of wire-cloth, say with ends and two sides wood, the other two sides to be of wire-cloth. One end of this will have a hole into which I can insert a large funnel, one large enough that I can shake brood-frames over it and thus box the bees, shaken off, by having them slide down through it into the cage. In this way I will draw bees from strong colonies at an out-yard, bring these bees home, thoroughly mix them and weigh out equal

quantities and put into two sets of prepared hives, supplying each of these new colonies with queens hived right in with them. The bees being caged and hauled home in the wagon, and without queen or brood, would be ready to accept almost any queen. To make things more sure I would feed them all the diluted honey (sweetened water) they would take, then the last thing before weighing out the divisions, give them a good mixing, then just let the queen run in with them.

The object in this thorough mixing is to get the bees of different colonies and bees of different ages all one conglomerate mass, all with sacs full, then to weigh out and divide would result in colonies that I know are alike. Bees thus handled and hived in the evening would be ready for business the next day, and start out very much as a swarm does. I consider such "swarms" very much less likely to attempt absconding than natural ones, yet, to make sure, I would clip the queens. They must also be considerable distance from each other far enough so that during the night they will not hear each other call, and pass from one hive to another.

Previous to bringing in these bees I shall prepare the hives they are to occupy. Four brood-chambers will be provided with one or two dry brood-combs, the rest of the space being filled with frames with starters or full sheets of foundation. I would use (at least I think I would) six frames Langstroth size or equivalent, filling the rest of the chamber with dummies.

On two of these hives I would put sections and full sheets of foundation, on the other two put ready-made extracting-combs. An excluder must be under the extracting-combs. The ready-made combs, by relieving the brood-chamber, will allow the colonies under them to rear more brood than those with sections, and to allow the queen to use the extracting-combs for breeding would still further unequalize the colonies.

I will also prepare four more hives, two to have starters only, both above and below, the other two to have complete combs throughout. It may be necessary to keep the supers off this second four hives till work has been begun in the brood-chamber.

There is one common difficulty with all these plans the unequal breeding. There would naturally be more brood in those hives having the most comb to start with. This could be overcome in a large measure by living with virgin queens just hatch; thus the entire lot would be without brood for about eight or nine days, at which time breeding would come along more nearly equal in the various colonies.

As usually is the case, however, in getting out of one difficulty we get into another. To have these swarms with virgin queens, they are not so likely to settle down and get regularly to work, and some of the queens are likely to be lost while mating. If all would stay by their hives and no queens be lost, the use of virgin queens would be much the more accurate or trustworthy test.

This would use eight colonies in the experiment. The bees used would be very like new swarms are forced swarms yet all are as alike as can be four brood-chambers just alike, all having one or two brood-combs apiece to form a brood-nest at once. Two of the four must work in sections, and the other two be given unlimited storage-comb, thus making a direct test as to which will store the most.

Of the second division of four colonies, two must build all comb in both brood and surplus chambers, the other two to have full sets of combs throughout so they do not have to build any comb. This second four hives being very opposites two to build all needed comb, and two to have no comb-building whatever ought to show quite conclusively the advantage, if any, in relieving a colony from comb-building.

However, to avoid the difficulty of the ones with combs getting a great mass of brood in excess of those having to build, it is essential that one of two methods be followed. They may be given virgin queens as before mentioned, or, instead, they may each be given a comb containing just a very little brood, but no queen given. If given virgin queens they would begin to have brood in ten days, but if given only a little brood to start with, they would be 20 to 25 days in getting new brood started time to pass over quite a honey-flow.

These methods would eliminate the swarming problem, and surely would give trustworthy data. How many will try it and report?
Farmer Co., Colo.

The Afterthought.

The "Old Reliable" seen through New and Unreliable Glasses.

By "COGITATOR."

"CLIMBIN' UP DEM 'GOLDEN' STAIRS."

COGITATOR doesn't deliberately want to "blow cold" on Comrade Golden's side climb-ways (page 33), but the impression produced on his mind is that they call for too much carpenter work to secure a very moderate advantage. The trouble with him is that he doesn't believe bees carry honey upstairs exactly as good little boys carry up stove-wood. He cogitates that usually a number of hours pass before the nectar is put into the cells at all. Probably under pressure of a rapid flow a good deal is put into the cells temporarily, to be taken out again later.

BEEES THAT "SMELL" THEIR KEEPER.

I rather think Mr. Whitney is running things to extremes a little (on page 36), in claiming that bees know their keeper by sense of smell. It is not *impossible*, however; and in cases where bees are handled very often it is probable enough. I can heartily agree with him (and the rest of the minority) that there is no need to abjure ordinary dark or black clothing when going among bees. If you *want* to dress in white, like an oriental sahib, why do so; but you don't have to at all. Color may make *some* difference.

MANY-HUED CLEOME HONEY.

See the Colorado convention (page 36) for an example of how provoking personal experiences can be when one wants the exact facts. On the question as to what is the color of the honey from cleome (Rocky Mountain bee-plant), some said it was green; others are referred to as calling it purple. Mrs. Booth, you will see, stoutly averred that she never got either green or purple honey, and yet lived in the midst of miles of cleome.

If cleome has such sharp little spikes on its blossoms as habitually tear bee's wings all into fringe, and if bees at work on it die prematurely, we shall not be anxious to have the plant spread in our direction.

SALTING BEES—STARTING RIGHT RHEUMATIC HOSS.

What an ingenious and easy way of salting bees J. E. Lyon gives on page 37! Just a little salt water on the alighting-board. Some soaks in, and soon all dries up; but the salt is there, against the bees want it, in a shape that it cannot readily get away.

He'll have to wait a hundred years yet that brother at the convention who wanted to start *right*, and avoid all changing of fixtures and methods.

Eight-frame hives and rheumatism go together in span, it seems from page 38. "Tator would leave the stable door unlocked for somebody to steal that off hoss.

PREDICTING NEXT YEAR'S CROP.

Good plan for us to watch out and see if "Iowa" (on page 39) is correct, or somewhere near correct, in his surmises. Bad for white clover, and no crop next season, if the fall freeze-up comes when the ground is dry. Good crop assured if the soil is well wet clear down before freezing. Some one will remark that we won't be able to do anything about it. Hardly correct; to be able to predict next year's crop will lead to considerable doing about it.

INDECENCY IN EXTRACTING-MANAGEMENT.

Surprising, and not altogether pleasant to hear, that so old and excellent a bee-man as Oliver Foster lets his extracting colonies have brood in every story (five stories sometimes). Very likely he thinks *he's* maintaining decency in extracting, but one-half the brethren will not, if queens have the run of the extracting-combs. Every few minutes filthy little dabs of larvae and larval food will fly out into that honey which we desire normally-minded folks to buy and eat as *nice* and *dainty*; but which they wouldn't touch with a pole if they knew the facts. Mr. Rauehuss promptly reminded the convention that a peculiar thin honey or feed, not fit for extracting (to say the very least)

is usually stored more or less right next to young brood. This stuff, which cannot be shut out, if we allow queens in the extracting-chambers, presumably contains the matter bees pick up about hog-pens and privies. Can we afford to let public indignation hang over our heads like the sword of Damocles—hung by a single hair?

HONEY-SELLING MADE SWEETER BY RELIGION.

Perhaps you noticed that E. T. Abbott (on page 43) says for us not to talk religion when retailing honey. I hardly think Mr. A. meant that as a fling of contempt for everyday religion. In fact, few things are meaner than sanctimonious talk for the purpose of convincing a stranger that he may confide in your honesty—and truthfulness. This rather common meanness is foolishness as well; for it usually increases suspicion instead of allaying it. Also religious *disputes* might waste time, and do harm instead of good. But surely a word of Christ *after business is disposed of* is not a thing to object to. And then there's the familiar honey-seller and the old customer, mutually knowing each other perfectly well, what earthly use is there of restraining conversation on the best-beloved topic of all—providing it is to both the best-beloved topic? And when one or the other says heartily, "Let us pray together before we part"—are you sure, Mr. Abbott, that you could preach a sermon that would do half as much good?

FIGHTING BEE-MOTH WITH ASPIC.

If aspic (page 42, par. 8) is materially better than sulfur to fight the bee-moth with, we shall be wanting to know what aspic is, and what it costs. Killing an extensive lot of larvae with sulfur is a difficult job.

A LONESOME COMMISSION-MAN.

The only honest commission-man in Chicago, eh? Please don't publish his name. If the public knew of him he couldn't possibly do justice to the business that would come—and then the dear people would denounce him as a rogue. (See page 45.)

BEES HUNG UP IN STRINGLETS.

That frame of bees building comb (on the first page of Jan. 20) is very lifelike indeed; but for the benefit of beginners one may point out two things which are not normal. Comb that bees are at work upon is all covered up out of sight. A slight puff of smoke, or some other means, has been used to get this little comb partly in view. The same cause also has made some of the bees that still cling to the comb stick their heads into the cells—as they were not doing probably when undisturbed in the hive.

"What in the world are they *doing*, hung all up in strings so?" is the question that perennially springs to the lips of spectators. And, as the books and papers seldom or never give any answer, Tator will take pity on you and tell you. They are not doing anything. They are just waiting for the forces of Nature, which are within their bodies, to do the work. And the work is secreting little flakes of wax (six for each bee), and at times ripening some honey also.

ANOTHER NON-EXISTENT FACT.

Do extra-strong colonies lose bees proportionally faster in spring than medium ones? If it is a fact, then Mr. Davenport's reasons for it (on page 50) seem sensible. (Bees of the latter all have to stay at home cold days, while from the former they fly, and many perish.) But let us not add another non-existing fact, to be accounted for, to our previous long list.

AMOUNT OF FRAMES TO PREVENT SWARMING.

And Mr. Davenport gives us a cogitation-provoking estimate on a matter concerning which we have few or no previous estimates. Of good comb, well placed, 24 frames the amount needed to make *sure* a colony will not swarm. As an opener, to start an investigation, this is serviceable.

[YOUNG QUEEN WITH THE PRIME SWARM.]

Comrade Mead's case of a young queen that went with a prime swarm, and left the old queen behind, is interesting, and seemingly genuine. (Page 51.)

DIFFERENCE IN FRONTING EAST OR SOUTHEAST.

On page 52, I respectfully object to Dr. Miller's answer of no difference between east fronting and southeast. We have to *pay for*, in shortened life and labor of our bees, all distressing experiences which they are subjected to—at least so Tator thinks. A southeast fronting, when bees are hanging out, roasts the bees from 12 to 2 on torrid days, when in hives with an east facing there would be comfort at those hours. Of course this is not a great thing; but

where it is just as cheap to save a trifle as it is to waste, we do ill to bluff the youngsters out of the right path, with our veteran air of "don't-care-a-continental."

SNOW AT HIVE-ENTRANCES—DEAD BEES IN WINTER.

Cogitator would start two conundrums on F. A. Snell's article (on page 51). Are we quite *sure* that a few inches of fresh light snow at the entrance is not a benefit—that is, so long as it does not get solid? Again, if all the bottom except the entrance were three inches deep with dry dead bees (brought from elsewhere), wouldn't that be a benefit to the colony? and can we get dead bees out in winter without doing decided mischief in several ways?

BEES TAKE NOTHING FOR GRANTED.

That was an interesting fact contributed by Prof. Gillette (page 54), that bees before adding to drawn foundation first nibble it all over, so much that its thickness is one-sixth less at that stage than when first put in. Not much inclined to take things for granted, are our bees.

FOUNDATION CONTRAST NEARLY A KNOCK-OUT.

And the final contrast is curious between ordinary foundation and drawn foundation. Bees reduce the base weight of the former from 22 to 46 percent. They *increase* the weight of the latter by 67 percent, mainly with wads of wax stuck in the corners in the effort to get the shape of the bottom more to their mind. The Professor would call the result, on the whole, favorable to drawn foundation—but the Tator, he would call it nearly a knock-out, so far as last year's samples go. Just let's wait for the samples of 1899.

COGITATOR.

CONVENTION PROCEEDINGS

Proceedings of the Colorado State Bee-Keepers' Convention.

(CONTRIBUTED BY THE SECRETARY.)

(Continued from page 103.)

AMOUNT OF STORES FOR WINTERING.

QUESTION—About what amount of honey should a colony of bees have, to go into wintering quarters with?

Mr. Adams—From 20 to 25 pounds, if in an 8-frame hive.

SPRING FEEDING—SEPARATING SWARMS.

QUESTION—Do you advise spring feeding?

It was suggested that it might pay in certain localities where fruit-bloom had started extensive brood-rearing, and a lull might otherwise ensue. Where there is no fruit-bloom, and sufficient stores are in the hive, bees will ordinarily build up without feeding. Pres. Aikin suggested that the bees be stimulated by extracting the combs, so that they will move the honey.

QUESTION—What is the best method of separating swarms if several or more should go together while swarming?

Mr. Whipple—Shake them on a sheet, and let them run in both hives.

A Member—Scoop some into each hive.

Mr. Elliott—I had read of a plan of having a long box with frames in it suspended crosswise, into which the bees are allowed to run, when they will separate of their own accord. I have tried it, and while it does not work in all cases, it does in a good many.

SEVERAL QUESTIONS ANSWERED.

QUESTION—Is it best to keep hives for wintering close to the ground, or two or three inches higher?

Mr. Honnett—I would advise the higher space, so that mice cannot get in.

Pres. Aikin—They should be high enough for the air to circulate freely, and so that an ordinary snow will not pile up about them.

SWEET CLOVER ON WASTE LAND.

QUESTION—Is there a law requiring sweet clover to be destroyed on waste land?

It was replied that a law including noxious weeds had

been past some years ago, but not enforced, and that the law was probably intended to cover sweet clover.

QUESTION. Suppose my neighbor takes a full case or two from a foul-broody colony, shall he be told it cannot be sold?

Pres. Aikin read Sec. 8 of the foul brood law, which forbids under penalty the sale of such honey.

HONEY LEAFLETS—CONSTITUTION AND BY-LAWS.

A little discussion then took place on the propriety of purchasing a quantity of honey leaflets, printed with the Association's name, for the use of its members. The idea was favored, and the suggestion made that each member could in addition stamp the leaflets he used with his own name.

The committee on Constitution and By-Laws (J. B. Adams, D. A. McLean, and Ben Honnett) made the following report:

"Your committee would respectfully report that after examining briefly the constitution we find that many important matters in it require revision, and require more time than is now at our disposal, and we would recommend that a committee be appointed to do this work and report at our spring meeting."

In accordance therewith, the following committee was appointed: J. B. Adams, A. F. Foster, and M. A. Gill.

GRADING OF COMB HONEY.

The report of the committee on grading, consisting of W. L. Porter, J. E. Lyon, Walter Martin, M. A. Gill, and R. H. Rhodes, was read and adopted. The Secretary requested the reporter to reword portions of it, so as to make it clear without altering the meaning, and in its revised form it stands thus:

No. 1. Sections to be well-filled, honey and comb white, comb not to project beyond wood, wood to be well cleaned; cases to weigh not less than 21 pounds net per case of 24 sections, but cases in lots must average 22 pounds net.

No. 2. Includes all amber honey, and all white honey not included in No. 1; to be fairly well sealed, and not weigh less than 18 pounds net per case of 24 sections.

CULLS. All cull honey shall be sold in the home market.

After the report Mr. Porter exhibited the honey which had been graded by the committee in arriving at their conclusions, setting each section up in turn, so as to be an object lesson in grading.

A section was then handed around which the committee could not agree upon, and a vote taken on its grading. Twenty-eight voted that it should go into the first grade, and ten that it should go into the second. The comb was white, straight, and well filled; but on one side, at the bottom, all of the first row of cells was empty, all but a few of the second row, five of the third, and one of the fourth. The trend of the ensuing discussion was in favor of calling it a second-grade section. It was urged that only a few cells were empty; but the replies were made that then it could not be called well capt, that it is hard to establish rules after going beyond one row of cells, and that another section, which was exhibited as undoubtedly a second-grade section, had no greater number of empty cells, only these were differently arranged, so as to form a patch, and thus be more apparent.

A double-tier case faced with nice white sections, with all varieties of No. 2 and cull honey behind the facers, was next exhibited, and created much merriment. It was marked "From the Rocky Mountain Apiary of Michael Snider, of Rocky Canyon, Colo." Probably but few present realized that it was a hoax, having been prepared by one or two members as an awful example of faced honey; but as such honey has actually been put on the market, it was no exaggeration.

Mr. Pease I don't see why No. 1 should correspond to Eastern fancy, if we sell to Eastern markets.

Pres. Aikin My idea of proper grading is No. 1, No. 2, and culls.

F. Rauchfuss The Washington grading cannot be lived up to. Its fancy grade requires the wood to be unsoiled, and its No. 1 grade that the combs shall be uneven or crooked, or otherwise defective. Now, here is a section with the wood just a little soiled, and the comb perfectly straight, completely capt and white. It is not fancy; it is not No. 1. What is it?

Mr. Pease Wouldn't the limit of 18 pounds for No. 2 allow pretty light honey?

H. Rauchfuss Good honey may be light.

F. Rauchfuss Words do not speak plainly enough. A good many members are absent. The only way better than

a description is to have representative combs of each grade photographed, and send the photograph to a bee-paper.

Mr. Carlzen We have honey that is better than that.

F. Rauchfuss—Then people will get something a little better than they ask for, and there will be no complaints.

By a vote of the convention, the committee were instructed to have a photograph made of representative sections of each grade.

OFFICERS AND COMMITTEES—RESOLUTIONS.

Officers for the ensuing year were then elected, as follows: President, R. C. Aikin, of Loveland; Vice-President, D. A. McLean, of Fort Collins; Secretary, Frank Rauchfuss, of Elyria; Treasurer, Mrs. R. H. Rhodes, of Arvada; Member of Executive Committee, W. L. Porter of Denver.

On motion of Mr. Gill, a committee of three, consisting of M. A. Gill, A. F. Foster, and D. A. McLean, were appointed to draft a vote of thanks to the Secretary for his services, and send the same to the bee-papers.

Other committees were appointed as follows: **LEGISLATION**—L. Booth, Senator Swink, Col. Whipple, E. Milleson. **EXHIBITS**—W. L. Porter, M. A. Gill, C. B. Elliott. **SUPPLIES**—Walter Martin, J. N. Pease, Philip Large.

Resolutions of thanks to Prof. Gillette were adopted for his lecture on foundation, to the Board of Capitol Managers for the use of the room, to the officers for their efficient work, and to the reporter; and other resolutions, also offered by the Committee on Resolutions, that the Association should feel grateful for the unwonted attendance and interest manifested, and for the harmony and mutual feeling between the members, and that the bee-inspectors should be ably sustained by the members of the Association in eradicating foul brood, were further adopted.

The convention then adjourned, subject to the call of the Executive Committee.

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, *Marengo, Ill.*

[Questions may be mailed to the Bee Journal, or to Dr. Miller direct.]

Seed of Rocky Mountain Bee-Plant.

Where can I get seed of the Rocky Mountain bee-plant?
AMATEUR.

ANSWER.—The seed-houses ought to be able to furnish it. Write to some of the seed advertisers in this journal.

Small and Large Hives—Queen's Laying.

1. Referring to the controversy in the Bee Journal about small and large size hives, and what a queen is capable of producing in eggs, I would like you to tell which is the more profitable, to give 10 frames to a queen capable of filling them with eggs, or 8 frames?

2. If this queen can keep 8 frames full for four years, would she be worn out in two years on 10 frames?

SUBSCRIBER.

ANSWERS. 1. That might depend somewhat on circumstances. As a general rule it might be better to let her have the 10 frames.

2. I don't believe she would, nor in three years.

Using Sections with Drawn Comb.

Which is best, to put on drawn sections of last year, without cutting them down some, or cut them down, and to what depth? They have never had honey in them.

SOUTH ALABAMA.

ANSWER. In very rare cases the comb of drawn sections may be so thick that it needs cutting down so the comb will not touch the separator. Generally, however, the only reason for cutting down or leveling sections is because the edges of the cells are soiled or discolored to a greater or less depth. If the sections are of the ordinary kind, with insets, lay a straight-edge across the section and see how

near to it the comb comes. If there is a space of about $\frac{1}{4}$ -inch between the straight-edge and the comb, and if the comb is nice, white and clean, then it doesn't need cutting down at all. If the edge of the comb is soiled, cut away all the soiled part, and no more. You say your drawn combs never had any honey in them. In that case the cells are not more than $\frac{1}{4}$ or $\frac{3}{8}$ inch deep, and unless they have been left on the hive a long time when not needed, they will be clean and not need any cutting down at all. If they are soiled enough to need any part cut away, it's very likely they are soiled clear to the septum and only fit to melt into wax.

Bees Affected with the Diarrhea.

I put my bees in the cellar and two of the colonies are affected with diarrhea. I have put them all outside now. What must I do for those that have the diarrhea?

MONTANA.

ANSWER. There isn't much you can do for them unless you can give them a good warming up. Perhaps you can in some way heat your cellar for a short time. But better do it at night, for if they get stirred up thoroughly and the least ray of light gets in you may have trouble. If you heat the cellar to 60 degrees or more, the bees will become greatly excited and will run all over the hives, but by the next morning they will be all quiet. To set them out when it is too cold for them to fly will only make matters worse. Better keep them where they are, and hope for a warm day.

Using Musty Hives—Full Foundation Sheets.

1. I have two old hives that I would like to use, but they have a musty smell and I am afraid bees will not stay in them. What can I do to the hives that will remove the smell?

2. Do you advise using full sheets of foundation in frames that will not last more than five or six years?

VIRGINIA.

ANSWERS.—1. If the hives are without any top fast to them, and if your hives with bees in them have loose bottoms, then put one of these old hives under a strong colony as soon as bees begin to fly in the spring, and by the time you want to use it the bees will have it all sweet and nice. If your hives will not admit of that, take the frames of comb out of the hive and let the hive stand a few weeks out in the sun and rain. If you want to make a shorter job of it, wet the inside of the hive pretty thoroughly with kerosene and set fire to it. Or you may scald and scrub the hive. The combs will still be musty, and you can get the bees to clean them by putting one or more at a time in one of the hives with bees.

2. I rather think it would pay to use full sheets of foundation even if the combs lasted only two or three years.

Now it's my turn to ask you a question. What's the matter with your frames that they'll last only 5 or 6 years?

Colonies Suffering for Air.

I am wintering 17 colonies in one end of a hen-house which is partitioned off to about the right size. I left about one inch entrance, and when I scraped the dead bees out from the bottom-board, I noticed an unpleasant odor, as of decaying matter, in some of them. The hive-bottoms are quite damp inside, also, and the bees inside do not carry the dead ones out. Can I do anything for them? Should they have fresh air?

2. What do you think of putting those colonies out early and packing them? If all right, when would you do this?

3. There are some rats and mice in the room with the bees. Do you think they will do harm? If so, how can I get rid of them?

ILLINOIS.

ANSWERS.—1. You do not plainly say so, but as nearly as I can make out, the bees have no chance to fly out even if a warm day should come. That's a bad job. From your description the bees are suffering for air. Instead of that 1-inch entrance, open up the entrance the whole width of the hive and clean out the dead bees, doing it quietly to disturb the bees as little as possible.

2. Very likely it might be a good plan to do so the first day the thermometer goes up to 50 degrees with the sun shining. Even at 45 degrees it might do if it is still. You can take one colony out and see if they fly well before taking out the others. But if it's up to 50 degrees and not too windy, the sooner all are out the better. After they

have a flight you can pack them, and it might be a good plan to take part in the cellar and see which do best.

3. Yes, rats and mice will destroy the combs badly and eat both honey and bees. You should have closed the entrances with wire-cloth having about three meshes to the inch. That would have kept the mice out. It will do some good to screen them now, for the mice will do more harm to be allowed free run than to be confined in the hives.

Swarming and Double Brood-Chambers.

1. Can you prevent swarming by the use of two 8-frame hives for a brood-chamber, taking one away at the approach of the honey harvest? If not, what percent cast swarms?

2. By what method, if any, do you control swarming other than the double brood-chamber system?

3. What numbers of frames does a colony fill with brood up to the honey harvest with the double brood-chamber system?

IOWA.

ANSWERS.—1. No, indeed. About the same number will swarm as if you had used only one story from the beginning, say about 100 percent in a good season.

2. Like a good many others, I'm feeling around in the dark after some satisfactory system, but not sure of anything. *Sometimes* you can prevent swarming by cutting out queen-cells, but you can't depend on it, and it's too much trouble. If you can re-queen your colony with a young queen reared in the same hive, it is possible you will have no swarming; but how to do that satisfactorily is the question.

3. From 6 to 12, counting the frame with the usual border about the brood.

Foundation in Brood-Frames.

1. Does your split bottom-bar work all right?

2. Do you let the foundation come down between the bars? and will the bees not stick it fast and bulge the foundation when it stretches?

3. If you prevent stretching with your sticks, why is not a solid bottom-bar just as good, and let the foundation come down to the bar?

SOUTH DAKOTA.

ANSWERS.—1. Yes, indeed.

2. The foundation comes down between the two parts of the bottom-bar. The bees don't stick it fast too soon, for it's held fast before the bees get it. The foundation doesn't bulge because it doesn't stretch. The little sticks prevent stretching.

3. A solid bottom-bar is just as good, if you cement the foundation fast to the bottom-bar. But if the foundation is at all loose from the bottom-bar, the bees will be sure to gnaw away more or less of it and have passages between the comb and bottom-bar. Even if fastened solid they'll sometimes do that. Putting the foundation between two parts of the bottom-bar is rather easier and surer than cementing with melted wax. Besides, you're sure of having the foundation exactly in the middle.

Temper, Hardiness and Beauty of Bees—Re-Queening—Comb from Black Bees.

1. Which is the gentler in disposition, leather-colored or five-banded Italians?

2. Are the golden Italian bees as hardy as the banded?

3. Which is the handsomer, the three or five banded?

4. What will be the price of queens in April? I want to re-queen.

5. Will the comb from a black colony do for Italian bees? I mean will the cells be large enough? KANSAS.

ANSWERS.—1. According to reports there is a good deal of variation among the five-banders, some of them being cross, while others are as gentle as the leather-colored, if not more so. The leather-colored are almost uniformly gentle.

2. Probably Italians having more than three bands are not alike with respect to hardiness, some of them being reported as not so hardy as the three-banders. Others may be just as hardy.

3. That's a matter of taste. To me the five-banders are much handsomer, and likely most would agree in that view.

4. Probably about the same as other years, from $\frac{1}{4}$ to $\frac{1}{2}$ higher than in June or later. Don't you think it will be pretty early to re-queen in April?

5. Yes, they are used indiscriminately.

EXECUTIVE COMMITTEE—Pres., E. Whitcomb; Vice-Pres., C. A. Hatch; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GEN'L MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

VOL. 39. FEBRUARY 23, 1899. NO. 8.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

The Chicago Bee-Keepers' Association will hold its third quarterly meeting Thursday, March 2, at the Briggs House, northeast corner of Randolph St. and Fifth Ave. Of course every bee-keeper is invited to be present, especially those in this (Cook) county.

Sweet Clover. Mr. Wm. Stolley's article on the sowing and growing of sweet clover will be found in this issue. Read carefully all he says about it, for he has had long and extensive experience with it, both as a food for farm stock and as a honey-producer. We can supply the seed of sweet clover promptly, as shown by the advertisement on page 123 of this number.

The "Feeling" Regarding Apis Dorsata. The American Bee-Keeper says:

"The American Bee Journal says, 'Apis dorsata is strongly championed by the American Bee-Keeper. Since those who oppose it say that it cannot prosper in this land, why need there be any feeling about its introduction?'"

The reply to this shows that the American Bee-Keeper understood the item as an argument against any attempt at the introduction of said bee. Editor Hill, you have clearly misunderstood the drift of the item, a misunderstanding that is entirely pardonable. You understood it to mean "feeling" on the part of those who desire its introduction, in which meaning there would be little sense and less argument. But please look at it in the way in which it was really meant, and you will probably see both sense and argument. The meaning was that there need be no

"feeling" on the part of those who opposed its introduction, and the argument might be paraphrased after this style, by those who were not trying to be careful of the "feelings" of the opposers:

"Say, you fellows that are raising such a howl against introducing Apis dorsata, what under the sun is the sense in it? You say it cannot prosper here, will die off right away if brought here, and if it is brought here only to die right away, what harm can that do *you*? Where is the sense in your showing so much 'feeling' about it?"

Lost Numbers of the Bee Journal are being reported as never before so it seems to us. We can't understand it, for we have mailed them regularly *every Wednesday evening* for years. It must be the cause of the many losses lies with the post-office—after the papers leave our hands. We are glad to replace all lost copies, if only they are reported promptly. We are extremely careful to mail the paper to every subscriber, and if they don't get it, we attach no blame to ourselves. Of course we regret the non-appearance, but can only offer to mail them again when so requested, and before the edition is exhausted.

The National Bee-Keepers' Union. We have received the following report of the recent election results, from General Manager Newman:

NATIONAL BEE-KEEPERS' UNION.

TO THE MEMBERS:—As many have requested copies of the report of the judges of election as soon as it is made, this is sent for information:

SAN FRANCISCO, CALIF., Feb. 8, 1899.

We, the Committee appointed by the Advisory Board of the National Bee-Keepers' Union to count the ballots cast for the various candidates for the year 1899, submit the following, to-wit:

Total number of votes cast 76.

FOR PRESIDENT—R. L. Taylor receives 44, G. M. Doolittle 16, scattering 14.

FOR VICE-PRESIDENTS—C. C. Miller 50, G. M. Doolittle 41, A. I. Root 40, Eugene Secor 27, C. P. Dadant 27, A. J. Cook 27, J. M. Humbaugh 10, Frank Benton 9, Chas. Dadant 9, E. K. Root 9, scattering 68.

FOR GENERAL MANAGER, SECRETARY AND TREASURER—Thomas G. Newman received 71, scattering 5. W. A. PRYAL, (Committee. F. N. BLACKMAN,)

As the Hon. R. L. Taylor and Prof. A. J. Cook positively decline to accept any office, the following, having received the highest number of votes, are declared duly elected: G. M. Doolittle, President; Dr. C. C. Miller, A. I. Root, Eugene Secor, C. P. Dadant and J. M. Humbaugh, Vice-Presidents; and Thomas G. Newman, General Manager, Secretary and Treasurer.

For 15 consecutive years I have been almost unanimously elected to the office of General Manager, and now I feel that, in justice to myself, this must be the last time that I can accept the office, and therefore request the members to unite upon my successor at the next election.

Realizing that my experience for 15 years will be of value to my successor, I will cheerfully give counsel at any time, or accept a position on the Advisory Board, or take the office of President if it is generally desired by the members. I wish to thank all for this renewed proof of esteem.

Yours respectfully, THOMAS G. NEWMAN,
General Manager.

1429 Market St., San Francisco, Calif.

We wish to congratulate all the successful candidates, upon their election to positions in an organization that has won so many honors in the interest of bee-keeping, and that has been so uniformly victorious for so many years.

Discouraging Situation in Southern California. Prof. A. J. Cook, writing us Feb. 9, from Claremont, Los Angeles Co., had this to say about the exceedingly discouraging prospects for bee-keepers in Southern California:

The honey situation in Southern California is certainly very discouraging. A drouth last year that utterly precluded honey-production is followed by a prospect of still greater drouth this present season. At Claremont, Los Angeles county, up to the present date, we have had less than four inches of rainfall, whereas we desire 15 to insure

a full crop of honey. Two such seasons in succession are not only discouraging to the producer from the loss of income, but they are disastrous in causing the destruction of the bees.

If we do not get heavy rains from this on—and some of long experience think it is now too late to save the crop even if rains come—there will be a tremendous mortality among the bees. Even one year of honey-dearth is serious, as so many colonies starve, but with two following each other in succession, there will be few colonies left, it is feared, to reap the benefits when good seasons with bountiful rains come again.

Southern California has much to recommend it, but this one drawback of scant rainfall is the one thing that causes foreboding and unrest. It is not the bee-men alone who suffer, but the ranchers and orchardists are also sufferers.

A. J. COOK.

Surely, the outlook for bee-keeping this year in Prof. Cook's section of California is very depressing. But all any one can do is to try to "make the best of it," and hold on, if possible. The good seasons will doubtless come again in due time, and those who are able to bide that time will reap the harvest. We know how valueless are simply words at such a time, but if anything can be said that will tend to inspire hope for the future, we feel that it should be said. Let us trust that the rest of the country may have a honey crop this year, and that old Southern California may ere long roll in sweetness again.

Mr. C. P. DADANT, of Hancock Co., Ill., wrote us Feb. 15:

"We have just had a good day for the bees. The colonies are strong, there is next to no loss, and you may say, 'Hurrah for the bees!' They appear to be in splendid shape."

Mr. G. M. DOOLITTLE, of Onondaga Co., N. Y., writing us Feb. 10, said:

"It is blowing very hard here, with the mercury 13 degrees below zero, and as we had about a foot of light snow on the ground, which fell yesterday, all our roads will be blockaded."

THE LEAHY MFG. CO., of Lafayette Co., Mo., wrote us Feb. 15 as follows:

"We have been having some very cold weather here—22 degrees below zero. For this part of the country this is extremely cold. Bees will be short in quantity in the spring, as hardly any one in this latitude protects them."

Mr. THOMAS G. NEWMAN, of San Francisco, Calif., writing us Feb. 9, reported himself as still in the doctor's care with little evident good. He said the weather there was cold also, but that it is worse for them to have the temperature at freezing than for the East to have it at zero, the air being so heavy and humid at San Francisco. We hope, as will thousands of Mr. Newman's old friends, that he will find relief in some way, and fully recover his health.

Mr. W. A. PRYAL, of Alameda Co., Calif. (near San Francisco), writing us Feb. 1, said:

"We have just had the hottest weather we ever had in January; it was for several days 75 degrees in the shade here; in the interior it was even hotter. It has been great weather for the bees. Honey was coming in so fast from the gum-trees that it seemed the bees had a pipe-line from the trees to the hives. Wild blackberries were beginning to bloom; so were the willows. Yesterday a change came; a big wind from the ocean blew in the clouds, and last night it commenced to rain. The weather is now quite cool. The warm weather was a little too good for this time of the

year. Vegetation, especially fruit-trees, were being forced along too rapidly; the frosty weather that is likely to follow later would have a disastrous effect upon the fruit-blossoms, or the young fruit. Still, we may have no more cold weather during the year."

JOHN BAUSCHER, JR., of Freeport, Ill., has issued one of the finest Poultry and Seed catalogs for 1899 that has come to our desk. It contains nearly 200 pages, is well illustrated, and contains much practical information. He mails it for 15 cents, and for 2 cents extra he will send a calendar. Better write him for both, not forgetting to mention the American Bee Journal when doing so.

IRA B. TRAVIS, son of I. A. Travis, of Walworth Co., Wis., died at Littleton, Colo., Feb. 1, where he had gone on account of ill health, being afflicted with asthma, which, by reason of taking several colds, developed into consumption. "Ira" was only a little over 21 years old, and an exemplary Christian boy, beloved by all who knew him. He was buried at his old home in Wisconsin. The Bee Journal extends sincerest sympathy to the bereaved ones.

OUR ADVERTISERS we believe to be entirely reliable in every case. If any of our readers find otherwise, we would consider it a favor if they would report it to us. We do not intend to accept the advertisement of a single irresponsible or dishonorable dealing firm. We hope our readers will extend their patronage to those who patronize our advertising columns, always remembering to mention the old American Bee Journal when writing to them. It will help both the advertiser and ourselves to thus mention this paper.

MRS. MATE WILLIAMS, of Wadena, Minn., is in sorrow by reason of the death of her beloved daughter, Jessie, who was a noble girl, popular wherever known, and was a valuable helper to her mother in the apiary and elsewhere, as well as a sweet and dear companion. Mrs. Williams is the conductor of the apiarian department of the Farm, Stock and Home, as well as a regular reader of the American Bee Journal. Our sympathy, as well as that of our subscribers, will go out to Mrs. Williams in her bereavement.

Mr. E. WHITCOMB, of Friend, Nebr., President of the United States Bee-Keepers' Association, has been delivering lectures recently on bees and bee-keeping, at local farmers' institutes. Of course he created much interest in the subject, just as the newspapers reported. Pres. Whitcomb is right "at home" on bee-keeping. And he can make it lively for his audience. He can dance and sing like an Indian, too. Probably the old Association never had such an all-around president. But he will need all his Yankee and Indian tactics when he comes to preside over the annual convention.

THE VON CULIN INCUBATOR COMPANY, of Delaware City, Del., have lately reorganized and doubled their former capital, and also added machinery to their present plant that will increase their present output of machines 50 percent. This was necessitated by the increased demand for their incubators in 1898, after they had added to their already high-grade machines their patented automatic ventilation and temperature regulators. It would pay you to send for their large catalog. Their factory is at 8 to 12 Washington Ave., Delaware City, Del. Don't fail to mention the American Bee Journal when writing them.

EDITOR E. R. ROOT, in Gleanings for Feb. 1, in commenting upon the improvements in some of their apiarian exchange papers, had this to say concerning the American Bee Journal:

"The 'Old Reliable' comes out with a new title-page, new body type (just like ours, by way of compliment), and one cannot fail to note an added freshness and vigor throughout the whole journal. It is the oldest of all the newspapers on this side of the Atlantic. It is a weekly, and always on time—the only one, I believe, that can really claim that distinction."

We make our very best bow for the foregoing compliment. Coming, as it does, from one who is so competent to judge, we can but appreciate it very highly, and continue to strive to issue a good bee-paper.

Izal for Foul Brood is championed by Editor Simmins in Bee-Chat, and a number of reports are enthusiastic as to its success.

Hand-Hole Cleats for Hives. H. R. Boardman and others have strongly preferred cleats to hand-holes for handling hives, and the A. I. Root Co. now announce that they are making a compromise—a short cleat directly over, and continuous with, the hand-hole.

Fruit, Bees and Poultry go well together. The bees, if the weather gives them half a chance, will see that every blossom of the fruit-trees is pollinated during the blossoming-time, and the chickens that have the run of an orchard, particularly of a plum-orchard, are worth all it costs to keep them if they never lay an egg.—Iowa Homestead.

Likes Big Hives but Not Big Frames.—N. D. West endorses most of what C. P. Dadant says about big hives, but is emphatic in his dislike of Dadant's large frames. He used them when first using frame hives; they winter well, give strong swarms, etc., but require a strong man to handle them all day long, and they are bad about breaking down when hauled over rough roads.—Gleanings.

Jamaica Bee-Keeping.—"Christmas pop," a white morning-glory which is the bellflower of Cuba, begins in November, and logwood last of December, the two lasting three months. Nearly all the honey is shipt to London, netting three to five cents. Hives must be at least two feet from the ground on account of toads, which are very large and swallow many bees if they have a chance.—H. G. Burnett, in Gleanings.

Blocking Up Hives at the four corners, together with equalizing and putting on sections early, prevented swarming for Mr. Bruce, as told by F. L. Thompson in a meaty article in the Progressive Bee-Keeper. The only two colonies that swarmed were induced thereto by superseding. But he thinks brood-rearing is hindered by blocking up too early. Mr. Thompson surmises that another reason for the lack of swarming was the much swarming of the previous year, giving so many young queens.

Wood-Zinc vs. Plain Sheet-Zinc Honey-Boards. J. H. Martin says in Gleanings that the wood-zinc are "infinitely better." R. Wilkin says he has been using the plain sheet-zinc for 10 years, has 700 of them, likes them, and wouldn't take the others and use them as a gift. He takes hold of the plain sheet at one end or corner, peels it off like a sheet of paper, with no snap to jar the bees, and no care to prevent breaking the wooden frame. If curved, turn the convex side up, and the super set on straightens it out.

Stimulative Feeding. Editor Hill, of the American Bee-Keeper, flings this somewhat defiant language at those who oppose stimulative feeding: "The doctrine and practice of stimulative feeding is not as popular as it was some 20 years ago; but, brethren, be it known, that yet a few of its old-time adherents are stalking up and down in the land, and the same satisfactory results are derived through its latter-day application that gladdened their hearts in the days of yore."

He probably takes comfort in the thought that he has a good deal of company the other side the water.

Why Are Large Hives Best? Editor Hutchinson quotes from Gleanings an article by C. P. Dadant with accompanying remarks from the editor of Gleanings, and then says:

"I have no doubt that in Mr. Dadant's locality and management a large hive is better than a small one. He must have found it so or he would use a small hive. Admitting this, I am still at sea as to the *why* of it."

He then brings up various arguments proving that the

large hive should be best, and demolishes them one after another, still leaving the question open, and demanding to know wherein he is wrong and what the real *why* is. This Boiler does not want to risk his life between the disputants, but would hint, Mr. Hutchinson, that you either forget, or have not seen, what Dadant has said about where the capital lies. You say it is not in the queens but in the hives and combs. Dadant says it is in the queens. So long as he holds that view, it is *why* enough for him to use large hives.

The Dickel Theory is one that is occupying a good many pages of the German bee-journals nowadays, and now occupies a page or more in Gleanings. The theory was advanced some 10 years ago, and is now revived and vigorously advocated by Editor Dickel. Dickel objects to the Dzierzon theory, and Dzierzon says the Dickel theory is nonsense. According to the Dickel theory, every egg laid by a normal queen is fertilized, and the workers determine the sex by the kind of nourishment given. The editor of Gleanings agrees with Dr. Miller, that it may be well to wait until the battle shall have been fought out in Germany before taking up much time with it here.

Do Bees Freeze?—Of late it has been bluntly asserted, especially in the agricultural papers, that bees never freeze, altho they may starve. Now comes W. Z. Hutchinson in one of the leading agricultural papers, Country Gentleman, and says that when he wintered bees out-doors in single-walled hives without protection, the bees came through in pretty fine condition in mild winters, but "in severe winters the bees in the outside spaces or ranges of combs died first; the cluster became smaller; the bees in more ranges died; and by spring all were dead" or ruinously reduced. It would be somewhat troublesome to show clearly that hunger and not cold was the trouble in such a case.

Large or Small Hives.—A. E. Manum is confident that in a poor season, and in a poor locality, a large hive is preferable to a small one. He says in the American Bee-Keeper: "I find that in a location where the honey season is short, that is, where the main dependence for honey is from clover and basswood, with little or none from fall bloom—nor but little is expected from fruit and other early bloom in the spring—that large hives are preferable to small ones, for the reason that the large hive will admit of sufficient winter stores gathered during the honey-flow coming from 'clover and basswood' to carry the bees through until another season's harvest without resorting to the sugar-barrel."

Out-Door Wintering is the subject of an able article by Editor Hutchinson in the Country Gentleman. He believes in packing four inches at the side and six on the top, using means to make bees fly on warm days if necessary. For packing material, chaff, leaves, planer shavings, dry sawdust. The best of all is cork-dust, but it costs. With a good, strong colony and abundant ventilation above the packing there is no trouble from moisture. To keep the packing in place, boxes of thin, cheap lumber, can be made to knock down for summer. Or, hives may be in a row with long box about them. He does not believe there is sufficient gain to warrant packing before freezing weather. Have a rim two inches deep under the hive with entrance above the rim. Then entrance can never be clogged. Weak colonies should be put into the cellar.

How to Know Honey is All Right for Feeding.—In the Canadian Bee Journal, page 476, appears the following:

"Look out for foul brood. A note of warning has several times been sounded by Editor Holtermann against feeding honey got from other beekeepers. The safe thing is to feed no honey unless you know it's all right." Beedom Boiled Down. Please, Mr. Boiler, will you tell us how we may "know it is all right?"

Mr. Holtermann, you must not ask this Boiler to tell how we may know, but ask Gleanings, the one that said it. It might be suggested, however, that we may know it is all right if we have saved it from our own bees or got it direct from some one who we know has no foul brood. But while your ear is at the 'phone, will you please tell us how such a strange metamorphosis came to be made in the item quoted by you? (On page 650 (1898) of the American Bee Journal it reads: "A note of warning is sounded in Gleanings," and you quote it as sounded by Editor Holtermann. Do such typographical errors occur in your locality, was the devil fooling with your copy, or how did it happen anyway?

Root's Column

In this department of last issue we showed you our super springs. We now show them a little more in detail, and how to put them in the supers. X is a curved piece of steel wire, one end of which is bent at a right angle, and sharpened. This is driven into the wood at a point that will come opposite the end cleat of the fence when in the super. After this is driven in, the other end is pounded down into the wood, making a sort of groove for the end B to slide in. Three such springs are used in our regular super—two to come directly opposite the end-

cleats of the fence, and one opposite the center cleat as at D, showing super side detach. On the opposite super side, and spaced in the same manner, are nailed three thin cleats, supplied with each package. These are to keep the outside fence a bee-space from the super side, about the same distance away as the springs do on the opposite side. We put in enough fences so that we have a fence between each outside row and super side. It costs a little more, it is true; but it carries out in effect THE PETTIT IDEA, or what he calls his divider—a method by which it is said the outside faces of the outside rows of sections are as well filled out as the faces in the center rows. Reports from bee-keepers last season go to show there is a good deal in this little scheme, and if so it may be worth dollars.

Keep Your Eye on this Column, as it may save you dollars.

The A. I. Root Company
MEDINA, OHIO.

GENERAL ITEMS

Succeeded the Fourth Time.

I tried three times to keep bees, getting no surplus and my bees dying. I bought "A B C of Bee-Culture" and commenced taking the American Bee Journal a year ago. I got 150 pounds of comb honey from two colonies, and no swarms. There was much honey-dew in the first taken off. Dark honey was the general complaint in this locality. The fall honey was very nice, I think, from smartweed.

I am well pleased with the American Bee Journal.
EVERETT BANTA.
Cass Co., Ind., Jan. 12.

Bee-Keeping in Jamaica.

My mother has an apiary of 180 colonies which I look after. I want to start an out-apiary of 200 colonies for myself this year. The honey season commenced Christmas day, fully a month earlier than we have ever known it. The logwood (*Hematorylon campechianum*) our best yielder and choicest honey, has commenced to blossom, and I want to send you a sample later, and get your opinion of it, and see how it compares with clover, sage, etc.

The Cuban vine, so highly spoken of by Mr. Poppleton, at Omaha, is commonly called "Christmas pop" in Jamaica.

Some time in 1899 I will send some of my experiences with the busy bee in the "Isle of Springs."
C. R. EDWARDS.
Jamaica, W. I., Dec. 26.

Past Year a Success.

The past year was quite successful with me. I got from 60 odd colonies 3,000 to 3,200 pounds of honey. The best colony stored about 90 pounds and from that down to 10 pounds of clover and basswood. It was just fine honey.

I have taken the American Bee Journal 8 or 9 years, and never have had one number miss.
JACOB MOORE.
Ionia Co., Mich., Jan. 5.

A Report from Maine.

I commenced in the spring of 1898 with 34 colonies and increased to 52. They built up well, but until June 15 they stored no surplus; then white and Alsike clover commenced to bloom and it yielded a good deal of nectar. The Alsike kept in bloom until the middle of July when it suddenly stopt. For about two weeks the bees could find nothing to work on, then they found some basswood three or four afternoons; when that source was suddenly denied them, presumably on account of dry weather. After that they scarcely managed to get a living, a little buckwheat and golden-rod yielding sparingly.

Breeding was suspended a good deal earlier in the season than common, and the bees went into winter quarters fewer in numbers than usual. I am looking for some losses this winter and spring, altho mine have plenty of stores, partly sugar syrup, and seem to be all right now on the summer stands.

My crop of honey amounted to 2,250 pounds of comb honey and 170 pounds of extracted.

I never had the boxes filled so full, many of them weighing from one to three ounces over a pound. I noticed most of the heavy ones were in colonies having young queens, and were somewhat in want of room. It could not have been done with older and more prolific queens, I think, as they would have swarmed.

I used five of the dovetail hives with supers of plain sections and fence, the past season, and I am well pleased with them. I did not give them a thorough trial, as I

Beeswax always wanted for cash or trade at the highest price. Address,

GUS DITTMER, Augusta, Wis.

did not get them in time, but I think I have never had sections filled and finished so fast as those were. But they are all a scant pound to the section—about 14 ounces on an average. For all that, they sell as readily as a section with insets, which weighs more.

We call the last honey season a good one for this part of Maine—the best, in fact, for many years.

I like the American Bee Journal very much, and would not do without it at double its present price.

Penobscot Co., Me. FRANK CHAMPEON.

Wintered Well Thus Far.

It has been snowing nearly all day, and the snow is about six inches deep, with good sleighing, for the merry sleigh bells can be heard far and near. My bees had two flights last month, the first they had was the first week in January, and the second Jan. 15; it was quite warm on that day so they had a good flight. I am glad to say that my bees thus far have wintered all right. But February and March are the two months in which bees need careful attention, as this month they begin to breed; however, I am afraid my bees are like the ground-hog that came out last Thursday from his winter quarters only to see his own shadow and then go back to stay six weeks longer. I have not seen anything of my bees since Jan. 15; this makes me think they are like the ground-hog, as they may stay in their house longer than six weeks. So all we bee-keepers can do at present is to carefully read every article in the bee-papers, and get ready for the coming spring by putting comb foundation in sections, painting the hives, etc. W. H. HEIM. Lycoming Co., Pa., Feb. 5.

The "Cake" Goes to Michigan.

EDITOR YORK:—You chose wisely when you took back what you said on page 28, for the reason that Mr. Murry has too many "backers." Now for a little sport, that is if you will agree to it.

I will buy of our grocer 1 1/2 pounds of comb honey, cut it out of the sections and place it on a plate with "knife," choose a man to eat the honey, call in six of our best business men for witnesses, and will leave \$1.00 with our banker, or send it to you to hold. If the man fails to eat the honey in 1 1/2 minutes from the time he commences, money is yours; if he does eat it in that time I have my \$1.00 back, and the "Old Reliable" one year free of charge. The one that gets beat pays for the honey.

I traded this man one two-quart Mason fruit-can full of extracted honey when he was a boy; he took it home, sat down and ate one good-sized loaf of bread, and the honey was just 1 1/2 inches deep in the bottom of the can when he finished his supper, or one meal. I timed him while he ate 15 ounces of comb honey this summer; it took him just 33 seconds, and he is not dead yet. Hillsdale Co., Mich. C. H. AUSTIN.

A Little Bee-Keeping Experience.

I have hunted wild bees for years. Two years ago I started saving a few colonies, and last fall I put 6 colonies into the cellar. They are hybrids and blacks, except the last swarm I found in a tree, which I transferred into the movable-frame hive, they are as yellow as gold, except their heads and the tips of their abdomens, which are black. What are they? Are they a good kind to keep?

I understand the handling of bees, but am not acquainted with the different kinds. These are a beautiful bee with golden bodies, tip at both ends with black.

I use the improved Langstroth-Simplicity hive, but I don't like them, for when I take off the supers it leaves a crack all around for bees to crawl out and bother. Please tell me the best way to drive bees out of the honey-boxes or supers when they are filled.

Last season was a very poor year for honey. I cannot remember a year that the

SEED DUE BILL FREE

To get new customers to test my seeds I will mail my handsome catalogue for 1899, lithographed and beautifully illustrated, and a 10c Due Bill, good for 10c worth of seeds for trial, absolutely free. It is full of bargains. All the Best Seeds, Bulbs, Plants, Roses, new Fruits, Farm Seeds, Potatoes, etc., at lowest prices. Ten Great Novelties offered without names. I will pay \$50. FOR A NAME for each. Don't buy your stock until you see this new catalogue, several varieties shown in color. Great inducements for orders this year. You will be surprised at my bargain offers. Send your address on Postal to-day. Tell your friends to send too. Old customers will receive a copy. F. B. MILLS, Seedsman, Box 88, Rose Hill, N. Y. Please mention Bee Journal when writing.

flowers were as thick as they were last year, but they did not have any honey in them. I found a number of bee-trees, and but very little honey, and part of that was not fit to eat, being very thin and watery. It tasted and smelt as if it came out of an apothecary shop.

Kandiyobi Co., Minn.

Poor Honey Crop.

The honey crop last season in this county was a poor one, owing to the wet weather in spring and drouth in summer. There was a fair flow of honey in the fall. My bees average only about 25 pounds to the colony. Some of my neighbors did not get nearly so much.

I consider the Bee Journal a great help to me, for I am a beginner, and my neighbors have had bees for years, but they do not read any bee-paper. That's where they miss it, else they would have better success.

The bees are wintering well, and have had several flights already.

R. C. SUPPE.

Woodson Co., Kans., Jan. 3.

Bee-Keeping in Oklahoma.

I have five colonies, and put them into the cellar in November. I carried them out three or four days ago, the weather being fine. They are all right so far.

I wish to ask in regard to bees in Oklahoma. I am about to sell out here and go to Oklahoma City. How do bees do in that country? If they do all right, I want to move mine there.

G. W. MAUK.

Jackson Co., Kan., Jan. 16.

[Will some of our readers who live in the Oklahoma country, kindly reply to the foregoing briefly.—EDITOR]

Last Two Falls Good.

The past two falls were the best since I have kept bees, and that is since 1856; 30 pounds was the most I had ever had per colony during golden-rod bloom until the fall of 1897, when one colony gained over 60 pounds in 13 days, and the past fall they gained over 30 pounds.

GEO. S. WHEELER.

Hillsboro Co., N. H., Jan. 12.

Bees Did Poorly Last Year.

I have taken the old American Bee Journal off and on whenever I kept bees for the last 15 years. I would not think of trying to keep bees without it.

My bees did very poorly last summer, but I put in 50 colonies in good condition, and they are all right up to date.

JOHN J. COX.

Chippewa Co., Wis., Jan. 10.

Bee-Keeping in Quebec, Canada.

I try to have about 20 colonies each spring. I live within eight miles of where Dr. Gallup, of California, lived when he bought the lucky swarm from the widow and gave for it the large quantity of lumber, that he told of in his articles on the recollections of an old bee-keeper, about a year ago.

I have a colony that I bought the first of last May, from a man living near the old mill that the Doctor and his father ran at that time. I believe they must be descendants of his lucky colony. They are in a big box, and last season they swarmed four times, beginning about the middle of apple-bloom. That old box colony and its four swarms gave me more surplus than any two of my Italians or hybrids and their swarms.

The first part of August I took all, or about all, the honey there was in all my hives except the old box—I could not get at that. I put my bees into the cellar the first of December, weighing each colony without the bottom-board. The old box weighed 68 pounds, and of the four swarms from this old box one weighed 44, two 45, and

Pointers for Poultry People

one 46 pounds. The Italians and hybrids ran from 40 down to 27 pounds. It is very difficult to find one of the native queens. The bees rush over the sides and out at the entrance as soon as I open the hive and give them a little smoke, and I think the queen goes with them. It is good of them to do this at extracting-time, but they seem to do best at comb honey. It may be that they steal the most of what they get, as they are bad robbers. They can do a big day's thieving when it is so wet and cool that the yellow bees will be lying around on the sidewalks, chilled. I am beginning to think there is no bee that equals the old natives for this climate.

T. R. WOODARD.

Richmond Co., Quebec.

Last Season Disappointing.

Many of us in this part of the world (northwestern Pennsylvania) were disappointed in not getting a large yield of honey the past season, notwithstanding the prospects were very bright last spring up to white clover bloom. Many of our beekeepers got no yield of clover honey, and a few got fair yields. My apiary averaged about 30 pounds per colony, one-half white honey, which sold at 12 cents, wholesale.

We are afraid our bees will get the grip, as well as the rest of us, for the unsteady weather cannot be good for them—at zero or below one day, and 40 or 50 above the next day is certainly not encouraging weather. Bees seem to be all right so far.

(GEO. SPITLER.

Crawford Co., Pa., Jan. 19.

Northern Honey Not Granulated.

Dr. Miller says all extracted honey that does not granulate may be looked upon with suspicion, yet I have some extrated honey that has been all winter where the temperature has not been above 40 degrees, and has been down as low as freezing for a week at a time, and the honey is all right now. Perhaps New Hampshire honey is an exception.

JAMES QUINN.

Strafford Co., N. H.

An Experience—Things Learned.

My past season's experience convinced me more strongly than ever that I don't know much about bees. When I reach New Hampshire, the middle of April, I found my five colonies packed in chaff cases had wintered so strong, and were working so fine. I felt like crowing long and loud, but like the goose of a rooster I was I never opened a hive until near the opening of apple-bloom, when to my surprise they were building queen-cells and about ready to swarm. I could not stay with them and hive swarms, could not consult Dr. Miller, as I had only five minutes to find out what to do. Well, I had to use something I call judgment, tho I did not have any—if I had, I should have looked after the bees in time. It was a poor season. I learned a few things.

One colony of Italians made progress all through the season, and when they had three stories full and sealed, I could exchange for empty combs from other hives and thus give the Italians room.

I secured one swarm, increase by the nucleus plan to 15, and packed them all up in chaff cases of my own make. Most of them were in two stories of 8-frame hives.

I reach Florida Nov. 1, and found 19 colonies alive out of 25 here. The fall flow was nearly over. I hurried through them, extracting four frames from each hive, and they nearly filled them again. I secured four colonies from trees in the woods.

I have learned that a wired frame with a starter put in the brood-nest, the new comb will be brought down over the wire all right.

I have learned that when a nucleus is left in one side of a hive behind a division-board, the balance filled out with frames and starters, the bees will cross the divi-

sion-board and work on all right, with the bee-master 2,000 miles away.

I have learned that a 5-inch rim between the brood-chamber and cover is a nice place to get chunk honey made without labor or attention, and a handy place to secure it compared with a hollow tree or even a frame hive with cross combs.

I have learned that you will get no poor queens reared above a bee-zinc with a good laying queen below. If the honey-flow is not sufficient none will be reared.

Now will some other greeny write about his blunders and mistakes? Perhaps while I was planning to run on the no-swarmer plan, and opening my hives for the first time with queen-cells all built, some other fellow was standing with swarm-catcher, spray-pump, and new hives—and never got a swarm.

EDGAR B. WHIPPLE.

Orange Co., Fla., Jan. 30.

Light Crop Honey Not Granulating

The honey crop was light here the past season. I got 1,200 pounds of extracted and 400 pounds of comb honey from 50 colonies, spring count—all fall honey. Prospects are better for white clover next season than they have ever been in my recollection. Can it be possible that

"Egypt" will yet be a white clover country?

Let me say here that Dr. Miller's answer to New York, page 7, does not hold good with me. The Doctor's answer would lead to the conclusion that all pure honey will granulate on the approach of cold weather. I have never known Spanish-needle honey to granulate unless there was a large percent of heart's-ease mixt with it. I never have my extracting-combs cleaned out when the extracting has been done late in the fall, yet the honey left in them does not granulate. I keep my unfinished sections, honey and all, for the next season's use, and have never had one to granulate, tho I would surely expect it if it were not Spanish-needle honey in them.

I would be pleased to hear from others on this subject, from Spanish-needle districts, through the "Old Reliable."

R. P. MAHON.

118 Michigan Street, CHICAGO, ILL.

HONEY AND BEESWAX MARKET QUOTATIONS.

CHICAGO, Feb. 16.—This month trade has been of small volume in comb honey, due perhaps to the extreme cold that has made transportation dangerous, we now look for a better movement; yet the season is drawing to a close, as after the middle of March there is practically none sold until the new harvest is ready.

Fancy grade of white comb, 15c; travel stained and light amber, 11 1/2c; amber and dark, 8 1/2c; candied and mixt colors, 6 1/2c. Extracted, white, 6 1/2c; amber, 5 1/2c. Beeswax, 27 1/2c. R. A. BOKSETT & CO.

DETROIT, Jan. 2.—No change in supply of honey as to quality, but prices are somewhat lower than last quotations, viz: Fancy white, 13c; No. 1, 12 1/2c; fancy dark and amber, 9 1/2c. Extracted, white, 6 1/2c; dark, 5 1/2c. Beeswax, 25 1/2c. M. H. HUNT.

INDIANAPOLIS, Jan. 4.—Fancy white comb, 12 1/2c; No. 1, 10 1/2c. Demand fairly good, Dark comb honey is being offered at 8 1/2c with almost no demand. Clover and basswood extracted, 6 1/2c. Beeswax, 26 1/2c. WALTER S. POWDER.

NEW YORK, Jan. 20.—Fancy white, 12c; No. 1 white, 10 1/2c; amber, 9c; buckwheat and dark, 7c. Extracted in good demand at unchanged prices. Beeswax rather quiet 27 1/2c.

Trade in comb honey is quiet. White is pretty well cleaned up, but there is a large stock of buckwheat, amber and mixt, having accumulated of late, and in order to sell in quantity lots it is necessary to shade quotations.

HILDRETH BROS. & SEGELKEN.

SAN FRANCISCO, Feb. 8.—White comb, 9 1/2c; amber, 7 1/2c. Extracted, white, 7 1/2c; light amber, 6 1/2c. Beeswax, 24 1/2c.

Market is not favorable to buyers, more especially for desirable extracted, stocks of which are decidedly light. Combs in moderate supply, and has to depend almost wholly on local custom for an outlet. Quotable rates remain as previously given.

BOSTON, Feb. 8.—The demand for comb honey is very light, with full stock on hand. We quote our market: Fancy white, 13 1/2c; No. 1, 12c; No. 2, 11 1/2c; light amber, 9 1/2c. No demand for buckwheat. Extracted, white Northern stock, 7 1/2c. Beeswax quiet at 27 1/2c. BLAKE, SCOTT & LEE.

KANSAS CITY, Jan. 25.—Fancy white comb, 13c; No. 1, 12c; amber, 11c; dark, 10c. Extracted white, 6c; amber, 5c; dark, 4 1/2c. Beeswax, 25c. C. C. CLEMENTS & Co.

BUFFALO, Jan. 27.—There is a little more activity in strictly fancy 1-lb. combs at 12c. The bulk of receipts of low grades sell at 10c, down to 7c, and in a few cases even less. A moderate amount can be sold every day. Extracted, 4 1/2c, according to quality.

BATTERSON & Co.

CLEVELAND, Jan. 2.—Fancy white, 13 1/2c; No. 1 white, 12 1/2c; No. 2 white, 11 1/2c; No. 2 amber, 9 1/2c; buckwheat, 8c. Extracted, white, 7c; amber, 6c; buckwheat, 5c. A. B. WILLIAMS & Co.

MILWAUKEE, Jan. 9.—Fancy 1-lb. sections, 12 1/2c; No. 1, 12 1/2c; No. 2, 11 1/2c; dark or amber, 8 1/2c. Extracted, in barrels, kegs and pails, 6 1/2c; dark, 5 1/2c. Beeswax, 25 1/2c.

The condition of the market is favorable for shipments of honey, especially of best grades, which are in small supply. The sales are moderate, but we are expecting an increased demand and good trade this spring.

A. V. BISHOP & Co.

Convention Notice.

Utah. The Utah Bee-keepers' Association will hold their regular semi-annual convention April 8, at 10 o'clock a.m., in the city and county building, Salt Lake City. A full program in the interest of the industry will be presented, and all bee-keepers are cordially invited. Among the subjects to be considered will be the purchasing of supplies, the disposal of our products, and the best method for the protection of the industry. It is desirable to have every county represented, either personally or by letter. Questions are solicited.

Hudson, St. Croix Co., Wis.

Please mention Bee Journal when writing.

IF YOU WANT THE

BEE-BOOK

That covers the whole Apicultural Field more completely than any other published, send \$1.25 to Prof. A. J. Cook, Claremont, Calif., for his

Bee-Keepers' Guide.

Liberal Discounts to the Trade.

UNION Combination SAW for ripping, cross-cutting, mitring, rabbeting, grooving, gaging, scroll-sawing, boring, edge-moulding, beading, etc. Full line FOOT and HAND POWER MACHINERY. Send for Catalog A.

Seneca Falls Mfg. Co., 46 Water St., Seneca Falls, N. Y.

THE WOOD BINDER.

THIS

Wood Binder

will hold one year's numbers of the AMERICAN BEE JOURNAL and will be sent by mail for 20 cents. Full directions accompany each Binder. The issues of the JOURNAL can be inserted as soon as they are read, and preserved for reference in book form.

By paying for a year's subscription STRICTLY IN ADVANCE this Binder will be sent, post-paid, for 10 cents extra.

ADDRESS:
GEO. W. YORK & CO.
118 Mich. St., Chicago, Ill.

22nd Year Dadant's Foundation. 22nd Year

Why does it sell so well?

Because it has always given better satisfaction than any other. Because **IN 22 YEARS** there have not been any complaints, but thousands of compliments.

We guarantee satisfaction.

What more can anybody do? **Beauty, Purity, Firmness, No Sagging, No Loss. PATENT WEED PROCESS SHEETING.**

Send name for our Catalog, Samples of Foundation and Veil Material. We sell the best Veils, cotton or silk.

Bee-Keepers' Supplies of all Kinds

Langstroth on the Honey-Bee—Revised.

The Classic in Bee-Culture—Price, \$1.25, by mail.

Beeswax Wanted at all times.

CHAS. DADANT & SON,

Hamilton, Hancock Co., Ill.

For Apiarian Supplies, Address,

LEAHY MFG. CO.,

Higginsville, Mo.
1730 S. 13th St., Omaha, Neb.
404 Broadway, E. St. Louis, Ill.

Eastern Bee-Keepers!

Do you expect to buy anything in the line of Apiarian Supplies the coming year? If so, we would be pleased to hear from you as to what you want, and mail you our Catalog. As we keep

Several Carloads of Supplies

in stock, we can ship promptly, and our location insures you low freight rates and quick transportation.

OUR HIVES, SECTIONS, ETC.

are made in Wisconsin where lumber is cheap and the best can be obtained. We keep Dadant's Weed Process Foundation in stock.

SPECIAL PRICES ON LARGE ORDERS.

Our apiaries are located at our home, Glen Cove, L. I., from which we sell Bees and Queens during the season. We have several yards of pure-bred, white Wyandotes, which we have bred for eggs, not fancy points. They are great winter layers. If you are interested in POULTRY, we would like to quote you price on eggs for hatching. We guarantee fertile eggs.

I. J. STRINGHAM, 105 Park Place, New York, N. Y.

7A18

BEE-SUPPLIES.

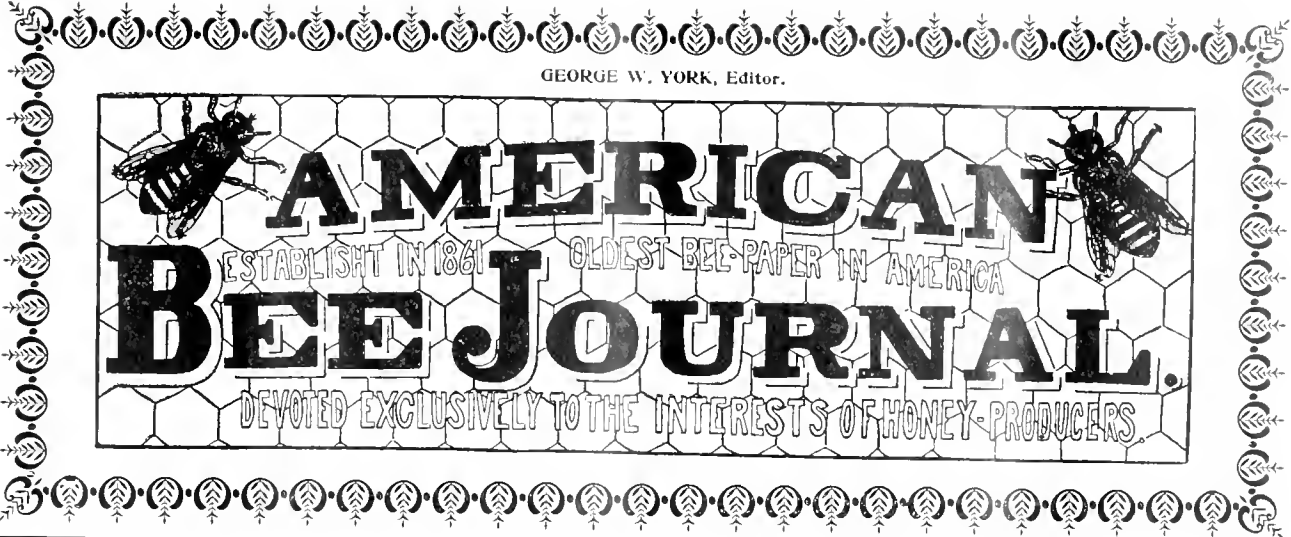

We have the best equip factory in the West. Capacity, one carload a day; and carry the largest stock and greatest variety of everything needed in the apiary, assuring best goods at the lowest prices, and prompt shipment.

Illustrated Catalog, 72 pages, Free.

We also manufacture Tanks of either wood or galvanized steel, all sizes, any form, for all purposes. Price list free.

Address, **E. KRETCHMER, Red Oak, Iowa.**

Please mention Bee Journal when writing.

AMERICAN BEE JOURNAL

ESTABLISHED IN 1861 OLDEST BEE-PAPER IN AMERICA

DEVOTED EXCLUSIVELY TO THE INTERESTS OF HONEY-PRODUCERS.

39th YEAR.

CHICAGO, ILL., MARCH 2, 1899.

No. 9.

CONVENTION PROCEEDINGS

Report of the California Bee-Keepers' Convention

BY JOHN H. MARTIN.

The ninth annual meeting of the California State Bee-Keepers' Association was held in the Chamber of Commerce, in Los Angeles, Jan. 11 and 12, 1899.

The meeting was called to order by Secretary McIntyre

at 2 p.m., Jan. 11. In the absence of Pres. Hatch, Mr. C. H. Clayton was elected President *pro tem*.

The first paper presented was by Mr. Geo. W. Brodbeck, on "The Bee-Keeper of the Future." The needs of better methods of management were pointed out, the results would be larger yields and a better quality of honey, all of which desirable results will surely come in the future.

The Secretary read the following paper from Mr. W. A. Pryal, after which followed a lengthy discussion:

Our Gigantic Honey-Producer - The Eucalyptus.

I do not want it understood from the title of this paper that the eucalyptus, or Australian gum-tree, is a gigantic producer of honey, but I wish simply to let you know that I consider it a great, big nectar-yielding tree of incomparable value to the honey-bee and her owner.

I have not seen a larger tree in America that secretes

Blue-Gum on Right (in bloom) Red-Gum on Left (the tallest of all) California Laurel or Bay-Tree (in lefthand corner) - Blue-Gums on the Hill at the Left.

nectar; I don't believe any one else has. Where is there a tree, often 100 feet high, in this country, that can be called a honey-tree? As far as I know, the basswood does not grow as high as our tall gum-trees, yet it secretes much more honey, at least in some years, as you know who have followed bee-keeping in the Eastern States. Possibly some day, when the gum-trees now growing in this State have obtained a good old age, they may be far superior honey-yielders than the basswood ever was.

We have bigger trees in this State than the eucalyptus, and I am proud to say that they are natives of California. Perhaps some day, when our eucalypti are old and hoary, they may be larger specimens of the vegetable kingdom than any of our sequoias of world-wide fame.

We Californians want to see everything about us spring into being with wonderful rapidity. We desire to prove to the world that we live in a fast age, and I think we do it. We have trees that in a few short years grow to prodigious size. "Jack's bean-stalk" would not be "in it" with some of these trees of ours. While I say our trees, still I would include some of foreign origin—the eucalyptus,

Blue-Gum (Eucalyptus) Flowers.

for instance. In the tree just named, bee-keepers are the most interested; it is one that overshadows everything else in their bee-garden, and as it is the one I started to discuss in this paper I must confine myself to it.

It is well that our delightful climate allows us to grow this tree, for it enhances the value of our State as a bee's paradise. With the aid of the honey from the eucalyptus an apiary that is located near a grove of these trees is able to bridge over a gap when other bee-pasturage would be an unknown quantity.

About the Bay of San Francisco, and more especially in the vicinity of Oakland and Berkeley where my observations of the tree under consideration have been principally confined, the blue-gum blooms in winter and early spring. The flowers are numerous, and I have known individual trees to begin their period of inflorescence in December and continue to bloom continuously until May or June. The buds on the south side of the tree are brought into bloom by the warm sun of December or January, and as the days grow more balmy the flower-cups expand in increased ratio until finally the whole tree has opened its honey-chalices to

the bees. It is a delightful pleasure to a lover of Nature to sit beneath a eucalyptus tree on a balmy day in winter, and listen to the myriads of bees merrily humming their glad tune as they industriously gather the nectar from the thousands of flowers overhead. With what vim they work is fully attested by their joyous hum and their rapid flight to and fro between hive and tree.

It is not long after the gum-tree begins blooming that the brood-chamber that was most depleted of stores during December—which, to me, seems to be the month when the bees consume the most honey in this climate—is again well provisioned. This honey is very dark in color, thick, and of a strong, aromatic flavor; the color often resembling the iron-colored sap that sometimes exudes from a cut in the tree and forms a gum of a rusty iron nature. And, in passing, I might ask, What honey gathered during the winter months in this State is light in appearance, and of a good marketable flavor? I know of none. Do you? My observations lead me to the belief that none of our honeys from native or imported plants yield light-colored honey, except in the warmer months of the year.

It is not a light-colored honey that the apiarist cares so much for during a year of drouth—almost "any old thing" at such a time will satisfy him and his bees. Where the apiary is located near a gum forest, or in a neighborhood where gum-trees are numerous, even if they are planted as roadside trees, as we find them in nearly all portions of the State, the apiarist's bees will not starve. They will be able to fill their hives with stores obtained from the flowers of these trees.

All through the winter, when the weather is fair, my bees work on the blossoms of eucalyptus globulus (blue-gum), and sometimes on eucalyptus rostrata (red-gum). It is not always that the latter blooms during winter hereabouts—more often its season of inflorescence is in the fall. Even then it is a boon to the apiarist, for it allows the bees to lay in a store of sealed honey for winter.

We could sow the seed or set out many plants that are noted honey-yielders, but how many do so? And this mainly for the reason that we consider the ground more valuable for some other crop. Where there is an abundance of water for irrigation, alfalfa is often raised, and an excellent honey-producing plant it is, too. Would that there were more of it in this State, for it would not only be a great acquisition for the apiarist, but for the cattle and sheep raiser as well.

Right here I would like to suggest to bee-keepers who have not tried it, that they fill their pockets with alfalfa seed when about to take a walk along the bank of a creek, or along the roadside, and then scatter some of this seed at intervals during their journey. By taking these little walks in different directions they will soon have seeded quite a section about their home. Most of this seed will grow, provided it is sown just before a rain. In a few years seed from the plants thus grown will scatter and become self-sown. The area of one's bee-pasture will be greatly augmented by pursuing this plan for several years.

There are many varieties of the eucalyptus in California besides the two I have already referred to, but I consider these the best for the bee-keeper, as they are of rapid growth, bloom profusely, and make excellent fuel. Eucalyptus globulus is well known; it is now about one of the most common and striking trees we have in the State. Eucalyptus rostrata is not so common. It is not quite so rapid a grower as the blue-gum, but it is generally of a handsomer appearance, if it is possible to attribute beauty to either of these trees. Some people are of the opinion that all varieties of eucalypti are ugly; this is far from being correct, for out of the several hundred varieties of gum-trees there are many that are ornamental.

Any bee-keeper who possesses a patch of land in the hills should by all means plant as many gum-trees as he possibly can, as I consider these trees very valuable for fuel, ornamentation (and God knows that our Southern California hills and some of the Northern ones, too—are quite desolate in their treeless nudity), enhancing the value of the realty; and last, tho not least, for honey.

Eucalyptus is of easy culture, and any one can raise the plants from seed. When the young plants are eight or twelve inches high, they are ready to set out in the place where they are to remain. They will require no attention after they have been in the open ground a year or two. I would recommend planting them in clumps of a dozen or so, rather than plant them at set distances through the field as one would plant an orchard. Clumps of trees at irregular intervals scattered over a field or hillside are more picturesque than when set out orchard fashion; besides, the

trees grow better; they do not have that bean-pole appearance that Rambler attributed to them once upon a time. In order to make them grow rapidly the first year or two after being planted in the open, and to prevent their being choked out by weeds, they should be cultivated.

I have been able to work my bees much closer since the advent of eucalyptus honey in my neighborhood than I was at any time previously. Before we had a flow of this honey there would be few wild flowers for the bees to work upon after the last of July. Now we have considerable honey from the red-gum during the fall. As there are five good-sized gum-tree forests in my vicinity—two being on the grounds of State institutions at Berkeley, and another of over 100 acres a few hundred yards away—perhaps I am too enthusiastic about these trees. Yet I hardly think I am, for I have given them a good deal of attention as honey-producing trees since 1877, as will appear from the old Bee-Keepers' Magazine and the Pacific Rural Press.

After March eucalyptus honey is not so dark and objectionable as that gathered during the preceding months—

from some Australian friend. He would raise a lot of plants from these, and in time they would be set out in his immediate vicinity. In and around San Rafael there are some fine specimens of eucalypti, one of which is, I believe, *eucalyptus ficifolia*, which produces a generous profusion of gorgeous scarlet flowers in trusses. It is one of the most handsome of the family; is rather tender, and on this account is cultivated more largely at the place named than any other place in this portion of California, because the climate of San Rafael is noted for its mildness. I have often seen ladies with large masses of these flowers as they wended their way from the San Rafael ferry in San Francisco. I should judge that the tree is a rich honey-producer.

At San Mateo, San Jose, and other places about the Bay, I have seen many varieties, and they all seem to be attractive to the bees. I should think there are more than two dozen varieties grown about Oakland. It was here, I believe, that the gum-tree was first planted in California; it surely seems to thrive better hereabouts than in any other place I know of. On our place we have a blue-gum

Blue-Gums in Winter—Red-Gums on the Hill at the Left.

at least that is my experience. Possibly in the southern counties of the State the honey from this source may be lighter in color, owing to the difference of climate. I am told that some of the honey gathered from these trees in Australia is very beautiful in appearance; that it is as light-colored as one could desire. Then I have been told by others that it is dark and disagreeable in flavor. I have not the least doubt that my informants are right; they came from different sections, and the climatic conditions being different, the honey was consequently affected thereby.

I have not seen any gum-tree honey that I could call light amber. Our light honey is produced after the eucalyptus has almost ceased to bloom.

I have noticed that in some portions of the State more of one variety of this tree is set out than there are of others, and that hardly any two places plant largely of a sort that predominates in another locality, excepting, I might say always, the everlasting blue-gum. What a hold this tree has on the affections of the people of this State! I suppose the reason of this uneven distribution is due largely to the nurserymen who introduced the trees in the different towns of the State. One man would get a collection of a few sorts

tree about a quarter of a century old, that is over three feet in diameter a foot from the ground, and something over 100 feet tall.

In the southern portion of the State I noticed a few varieties of eucalypti that I had not seen up here. I shouldn't wonder but they may be better honey-producers than anything we have hereabouts.

Over a score of years ago a bee-keeper in Los Angeles county asserted that the honey of a certain variety (he called it *eucalyptus ekostrata*) of gum-tree near the City of Angels yielded a nectar that poisoned all bees that sipped thereof. The Herald of that city exploited the matter. It appeared that it was slaughtering bees by the million; that it bid fair to destroy every bee near the city. My attention was called to the article by the editor of the Pacific Rural Press, and I was asked if I ever heard of eucalyptus honey killing bees. I answered that I had not, and I doubted very much if nectar from any plant was injurious to bees. After several more squibs in the local papers of Los Angeles, the matter was dropped, and I have heard nothing since about gum-tree honey being injurious to bee-life.

In closing, let me advise bee-keepers, especially those

who have plenty of unimproved land, to plant eucalyptus trees wherever and whenever they can. Those who have little room may plant out what trees their land will accommodate. Raise more plants than you require for your own use, and give the surplus ones to your neighbor to plant. He may be glad to get them, for he may have been wishing to establish a windbreak behind his barn, or, perhaps, he had been thinking that he should set out a lot of trees that would give all the fuel and fence-posts he and his children would require in the future. Just cast your bread upon the waters and it will return a hundred fold.

W. A. PRYAL

Mr. Brodbeck practices migratory bee-keeping, moves his bees from the sage-fields in the mountains to the suburbs of the city where the bees have access to a large acreage of the eucalyptus trees; the bees get enough honey to keep them through the winter, and sometimes they store a surplus.

Mr. Steele recommended eucalyptus robusta as a good honey-producing tree. It required great care to start the growth of the tree from the seed. The seed should be sown in fine soil in trays, and covered lightly with fine soil, and exposed to warmth and moisture. The young tree, when first planted, requires some nursing with water for a few years, but when it becomes fully rooted it will take a very severe drouth to kill it.

METHODS OF FEEDING BEES.

Methods of feeding were discussed by M. H. Mendleson and others. Mr. Mendleson crowds the bees upon a few combs, compelling them to crowd the queen into small space; by so doing the queen is prevented from enlarging the brood-nest and rearing a large number of bees to consume the temporary stores given them. He used for a feeder a half of a five-gallon can in which a float is placed.

Mr. McIntyre used a six-pound feeder on the rear of his hives, the bees having access to it through an auger-hole. The feeder has a cover to it, and there is no chance for robbers to molest the colony—they would make no attempts to gain an entrance in front of the hive.

Mr. Aldrich feeds at every tenth hive; to this colony he gives all of the feed and distributes combs as fast as they are filled to the colonies that most need the food.

Mr. Wilkin found that bees could be fed nicely at night, by tilting up the front of the hive and turning the feed in at the entrance, the bees taking it up from the bottom-board.

The session of the Association on the morning of the 12th showed some signs of dwindling. Altho the attendance was not so numerous, the discussion of foul brood laws and foul brood was quite animated, and consumed a good portion of the forenoon.

The question was asked if the bee-keepers would make an exhibit at the Paris Exhibition. As no concerted action was taken it will probably remain an open question, and made, if at all, upon individual contributions. California has never made a creditable exhibition of honey as representing the whole State, and probably never will until the advent of that "sweet bye-and-bye" referred to in the opening paper by Mr. Brodbeck.

MARKETING HONEY AND CO-OPERATION.

Mr. McNay, of Wisconsin, was present, and gave an interesting talk on marketing honey. He stated that nearly all of the Eastern honey is put in up barrels and kegs, and dealers prefer Eastern honey in that style of package. He advised bee-keepers not to ship honey to commission-men unless they got a good advance upon their honey. Honey that is sent on without exacting an advance, is usually put in the back portion of the warehouse, and is the last to be sold; that is the reason why bee-keepers sometimes have to wait so long for their returns. He found that where extracted honey was put upon the market, and where people could have confidence that it was the pure article, it would sell better than comb honey, and the sales could be increased. As there is a difference in tastes, and as some people like a strong-flavored honey, he could sell buckwheat at the same price as the light-colored and milder-flavored.

Mr. R. Wilkin, our well-known veteran bee-keeper, gave an interesting address upon "Co-operation." He had noted a great improvement in honey-production since 1861. Since that period more conventions were held, and journals published, and they all had an influence to elevate the business of bee-culture. The person who did not read the bee-papers, or did not attend the meetings of an association, obtained a second-hand knowledge of the business. Bee-keepers are

proverbial for their generosity in imparting their knowledge. His idea was that we should come together often, and trust each other more, and the result would be in a better class of bee-keepers. He indorsed the labors of the United States Bee-Keepers' Association, and hoped all would join the organization.

Mr. Wilkin was elected President for the coming year, J. F. McIntyre re-elected Secretary, and the present Treasurer continued.

A short honey season is not conducive to a large attendance at a bee-convention in California. Fully 50 percent of the bees have died, and the rains have not been sufficient encouragement to ensure a honey crop.

Los Angeles Co., Jan. 21.

Winter Flights for Bees—Constipation.

BY C. P. DADANT.

WE are having a good winter for the bees, tho it is a poor season here for the wheat-grower. There has been but little snow, but the alternatives of cold and warmth have given our bees repeated chances for winter flights thus far. It would now be very strange if the bees did not winter well. The early and rigorous cold weather of November and December threatened us with a long winter, but January proved to be mild, and the severe but short cold spell of February has not done them much harm.

Bees are a warm-blooded insect, and as long as a colony keeps in health the temperature of the cluster is about the same as the normal temperature of the blood of a human being. So the bees go safely through some of the most extreme cold-spells, even with a great deal more ventilation than one would think was good for them.

We had a neighbor bee-keeper, years ago, who kept bees in the old-fashioned way, and allowed them to go through the winter without a bottom-board, the hives being raised from the ground on stakes, and his winter losses were not much greater than the average. He held that they wintered better in that way, as they never lacked ventilation and pure air, which was true, but it always seemed to me that it was like sleeping with a window open. I know of people who never sleep without an open current of cold air. I never could become quite convinced that this was the proper way to avoid colds and catarrh, altho I will acknowledge that a change of air is necessary, or rather, indispensable, but I want mine warmed up before it reaches me, during zero weather at least. Tho our bees are in no fear of catarrh and cold, the protracted cold and extremes of temperature compel them to consume an unusual quantity of stores, and their abdomens become distended with fecal matter which they must discharge occasionally, if they are expected to keep healthy and winter well.

So an occasional warm day, allowing them to take wing and cleanse themselves, is always beneficial, and it may be safely asserted that with a warm day once every three weeks, ordinary colonies will live through the most frigid weather that is known in our latitude. When the cold weather is of long duration they are not only in danger of being compelled to discharge their bowels in the hive, but are also running the risk of constipation. And, by the way, this constipation which, in some years, seems to take the shape of a contagious disease, is but little seen outside of long confinement. I have often thought that the disease generally called "the nameless bee-disease," might be but a contagious form of constipation.

Cheshire, who has made an anatomical examination of this disease, gives it the scientific name of "bacillus gaytoni," after Miss Gayton, who, it seems, called his attention to it. In constipation, as in the "nameless," the bee is apparently crippled by the distended condition of her abdomen; when the contents of the bowels are examined, they are found loaded with offensive matter as foul as that discharged by healthy bees that have been confined a long time in the hive. The disease seems to be most prevalent among the oldest bees, for in most cases the sick ones are

those which are deprived of hair by long toil, and are "slick and shiny."

It has been suggested that the slick and shiny appearance was caused by the disease itself and only a result, but I have often seen young bees, with all other appearances of health and a full coat of hair, suffering from this same malady. When constipation has been prevalent in a colony, it seems to retain its hold among the bees, and to continue slowly and contagiously, and I have often known even the queens to die of the same cause. Occasionally the "nameless disease" has run with more or less force in a hive for an entire season, tho not with sufficient virulence to endanger the strength of the colony, but I am of the opinion that it may usually be traced back to the long winter confinement of the bees on perhaps inferior honey.

Plenty of good, well-diluted, warm feed in the spring, is the best thing that can be recommended to do away with this disease, but it is certainly advisable to procure our bees as many chances of flight as possible during the cold weather.

We have just had a pleasant day (Feb. 15), and the bees have again had a good cleansing flight. Every colony is alive in the home-apiary to-day. Surely the loss cannot be great.

Hancock Co., Ill.

No. 1.—Doolittle's Talk on Bees at a Farmer's Institute in New York State.

BY REPORTER.

JANUARY 18 and 19 there was a Farmer's Institute held at South Onondaga, N. Y., about 10 miles out from Syracuse. Among the other speakers announced on the program was Gilbert M. Doolittle, who was to be the last speaker for the afternoon of the first day. Besides the address of welcome in the morning, there were to be two speakers in the forenoon, and in the afternoon ex-Gov. Hoard, of Wisconsin, was to address the institute preceding Mr. Doolittle.

But the meeting opened late, and for this reason the first speaker of the forenoon took up all the time before dinner, thus crowding three speakers into the afternoon session. The first took an hour and a quarter of time, and the Governor an hour, so that it was nearly four o'clock when Mr. D. took the platform and lookt over the tired audience which had been assembled for about two hours and a half.

Mr. Doolittle's face showed that he was in a "brown study" for a moment, as if he feared he could not "catch and hold" his hearers with the subject, "Bees and Honey," which had been assigned him, when in their tired condition, for quite a few had been going out before the Governor closed his address. But presently a light came over his face, and he began something like this:

A little boy was sent to a neighbor's by his mother, one dark night, on an errand, and this little boy was always afraid in the dark. When he returned, his mother said to him, "You were not afraid much, were you, my son?"

The boy replied, "Oh, mamma, if you had only felt the streaks of scaredness run up and down my legs as I did, you would know I was scart."

"And now to follow two such eloquent speakers as have preceded me this afternoon, and especially a Governor of a great State like Wisconsin, makes the 'streaks of scaredness' run up and down my legs, just as they did on the legs of that little boy."

Here Mr. Doolittle gave a great shudder, which caused a smile to come over nearly every face, and from that time on Mr. D. had perfect power over those before him, so that no one left the room till he had finisht speaking.

He went on to tell how he was raised in "old, cold Spafford" (as the town of Spafford in which Mr. D. lives has the highest elevation in the county of Onondagal, where it was so cold they could eat "jack-wax" off snow-banks on the Fourth of July, and raise flax to perfection. How his parents moved to that town from the State of Connecticut, and being poorly supplied with this world's goods, kept him at work on the farm, so he had only a limited district school education. How one day, when the school commissioner came to examine the school, his teacher had pointed him out as "the biggest ignoramus in the school," and, said Mr. Doolittle, "he might have added his name is Doo-little."

This caused a ripple of mirth to pass over the audience, when he continued:

"But I am not here to tell you of my scaredness, of my

home surroundings, or anything of the kind, but to speak to you as best I can, in my homely, ungrammatical way, about bees and honey."

He then went on to tell how each good colony of bees in early spring contained a queen, and from five to ten thousand workers. The worker-bees are the ones which do the stinging, gather the nectar from the fields, nurse and feed the larvæ, build the comb, etc.; while the queen is simply the "mother-bee," her only business being that of laying eggs. When she first commenced to lay in the early spring she only laid about ten eggs a day, but as the weather grew warmer she made an increase, until, when doing her best, she would lay from two to three thousand every day during the forepart of June. These eggs were in that form for three days, when they hatcht into little worms or larvæ, so small as hardly to be seen with the naked eye, but, under the stimulus of the chyle fed to them then, grew till they nearly or quite filled the cell six days after hatching, when the cell was sealed over, and they remained in the pupa form, or hid from view, for 12 days more, when they emerged a perfect bee.

He told how the young bees did little more than eat and straighten out for the next day or two, when they went to feeding the larvæ, building comb if needed, and doing general "housework," till they were 16 days old, when they went out as field-workers, gathering honey, water, pollen and propolis, till 45 days from the time of emerging from the cell, when, as a rule, during the working season, they died of old age, and another generation took their place. Thus the workers lived 45 days only in the summer-time, but in the winter, when they were comparatively inactive, their vitality was not worn out so soon, hence the bee that emerged from its cell in September lived over till the next May or June.

As the bee was 3 days in the egg form, 6 days in the larval form, and 12 days in the pupa form, making 21 days from the egg to the perfect bee, the queen could place on the stage of action two and one-seventh generations to where one died off, thus bringing about swarming through her more prolific egg-laying during May and June.

He next told how by reversing and spreading the brood the queen could be coaxed to lay a greater number of eggs than she otherwise would, and if planned rightly, so that the greatest number of workers were on the stage of action at the same time when the honey harvest was at its best, the best results could be secured in honey.

He explained how to know when the honey-producing flowers would bloom, and how to rear the bees so as to meet this bloom; but to go into all of the minutia of what he said would take too long to be interesting to the reader. He reminded the audience that few bee-keepers paid much attention to this, which was the most essential point to be lookt after in producing honey. In fact, he made it very plain that the person who did not look after this part of the business could not possibly secure the best results in apiculture.

At this point he took the audience by surprise with a story something like this:

There was a certain darkey in the South who went almost daily to his nearest city to vend the proceeds from his truck-garden. But one morning something unusual happened, which was that his wife went with him, for the first time. As he reacht the suburbs of the city he called out in his usual way, "'TATOES! 'TATOES!'" Mr. D. here put such power in his voice that quite a number jumpt in their seats, and one girl gave a little shriek, which only added to the merriment.

Immediately the darkey felt something pulling on his coat-skirt, and his wife said in a hoarse whisper, "Hush, hush, honey; you'll waken everybody in town." To which the darkey answered, "'Do you suppose any one will hear me when I say 'TATOES!'"

"Hear you, hear you, yes! they'll hear you all the way for five miles around!"

"Well, that's what I'm shouting for. 'TATOES! 'TATOES!'"

This story brought a general applause, and as soon as it had subsided Mr. D. imprest upon his audience that such shouting, about bringing the bees and honey harvest together, always brought success to the one practicing it.

He told them how he might talk to them about swarming and non-swarming, queen-rearing, crating and marketing honey, preparing for winter, etc., but if they would take home with them one thought of securing the bees in time for the honey harvest, both he and they would be well paid for the time spent in coming to the institute.

(Continued next week.)

Italian Honey vs. That Stored by Blacks.

BY EDWIN BEVINS.

WHEN I first read the article by Mr. Bates on page 19 I said to myself, "The committee appointed to investigate and report on the causes for the superior quality of Italian honey is making progress." Then I "read over again that perplexing epistle," and concluded that not much progress had been made, after all.

It may seem ungracious in me to maintain so persistently the character of a Doubting Thomas, but as long as I am a skeptic I will not try to appear to be something else. When the evidence is such as to produce conviction I will own up as freely as Thomas did.

And now let us analyze the evidence adduced by Mr. Bates.

He says, "The taste of the pudding is the proof," leaving us the inference that he has tasted the two puddings made by the two different cooks, and that the pudding made by the Italian cooks had an appreciably better taste than the one made by the black ones. Now, I am not going to contend that one pudding did not taste better than the other. It is not the fact that one tasted better than the other, but the reasons for this better taste that we are in search of.

In his third paragraph, Mr. Bates relates the circumstances that a few years ago he had two colonies of blacks located side by side and apparently equal in all respects. One colony stored surplus, the other consumed the honey it had. His conclusion is that the difference in the "reach" of the bees of two colonies made the difference in results. It is then a fair conclusion that *some* colonies of blacks have longer tongues than do other colonies of blacks. If this be so, may it not well be that some colonies of blacks have tongues as long as some colonies of Italians? That the average length of the tongues of Italians may be greater than that of the blacks may be a proven fact, but I confess that I am not familiar with the proof.

In his seventh paragraph, Mr. Bates tells us that one season he had a 3-frame nucleus of Italians which beat an 8-frame colony of blacks. He attributes the difference in production to the difference in the reaches of the two strains, and also the difference in the quality of the honey. With what did he compare the Italian product? He says that he got not a pound of surplus from the blacks. But then he might have had other colonies of blacks that stored surplus.

I think that if Mr. Bates kept none but Italian bees he would some seasons observe similar differences in production between different colonies; and similarly if he kept none but blacks. So many factors contribute to produce differences in both production and quality that it will not do to attach much importance to any one of them.

There is some plausibility in the theory of Mr. Bates, that the better portions of the flower-secretions go to the bottoms of the flower-cups, and this would make me wish that these better portions would rise like cream instead of settling like a sediment, if it were not for the fact that the flower-cups of many flowers are bottom side up.

The facts recited by Mr. Bates in his third paragraph seem to be fatal to many of the claims and contributions embodied in his article.

Like the member of a certain fraternity (which shall be nameless), I am hungering and thirsting for "more light."

I do not now question the fact of the better taste of the product of Italian bees this fact is attested by so many credible witnesses that I am constrained to yield it my belief. But that this superiority is present at all times and under all circumstances may well be questioned. I would be understood as not being satisfied with the reasons thus far given for the existence of this better taste when present.

It is my impression, however, that when this discussion is over, it will generally be agreed that the reasons presented by C. P. Dadant are the reasons which come nearest affording a solution of the problem.

Decatur Co., Iowa.

Langstroth on the Honey-Bee, revised by the Dadants, is a standard, reliable and thoroughly complete work on bee-culture. It contains 520 pages, and is bound elegantly. Every reader of the American Bee Journal should have a copy of this book, as it answers hundreds of questions that arise about bees. We mail it for \$1.25, or club it with the Bee Journal for a year both for only \$2.00.

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(Questions may be mailed to the Bee Journal, or to Dr. Miller direct.)

Number of Bees in a Pint.

How many bees are there in a pint? As many claim that 40,000 bees make a good colony, I would like to know on what plan to estimate, so that I can tell when I have from 20,000 to 40,000. If I know how many there are in a pint I can estimate a colony.

PENNSYLVANIA.

ANSWER.—According to Root's "A B C of Bee-Culture" there are about 1,600 bees in a pint.

Number of Colonies in One Apiary Two Queens in One Hive Storing Syrup.

1. How many colonies will do profitably in one apiary?
2. Can there be two queens kept in one colony by having a queen-excluder between, with one entrance?
3. If syrup is fed to bees and they store it in the cells will it be honey or syrup?

OREGON.

ANSWERS.—1. That depends on the amount of pasture. J. F. McIntyre, in California, had 600 colonies in one apiary. It is quite possible that a less number might give more surplus, and it is entirely certain that in the large majority of locations 600 colonies would not only yield no surplus but would starve for want of food. It is estimated that a colony consumes about 60 pounds of honey in a year, and that 60 pounds must be taken from all that is gathered before any surplus is left for you. There is no way to determine positively how much nectar is in a certain territory, but suppose 6,000 pounds of honey is the entire amount that can be gathered by the bees in a given apiary. If there are 100 colonies, they will need for their own use the whole of the 6,000 pounds, and you will have no surplus. If there are more than 100 colonies, they will starve unless they are fed. If there are 50 colonies, they will need for their own use 3,000 pounds, and the remaining 3,000 you would have in surplus. If you have a fair amount of white clover or linden, with fruit-bloom and some fall flowers, it is probable that 100 colonies would do well, but it must be remembered that no two years are exactly alike.

2. You can have two queens in a hive by having a thin board partition between the two, and the two queens will sometimes, perhaps generally, be allowed if an excluder is between.

3. If bees are fed syrup in the ordinary way, whatever they store will still be syrup.

Transferring—Preventing After-Swarms Fence and Plain Sections.

1. In transferring, would you advise the Heddon plan as described in "A B C of Bee-Culture"? If so, how should the second "drive" be united with the first at the end of 21 days, as I presume they will have reared a queen of their own in the meantime?

2. To prevent after-swarms, I see you advise setting the swarm on the old stand, leaving the parent colony close to it for a week. The "A B C of Bee-Culture" recommends placing the old colony at the other side of the yard at once. What are the reasons for the different plans, and why will either plan stop it?

3. I am thinking of adopting fence and plain sections this year. Would you advise doing so, or sticking to the old style? Which of the plain sections would be better—the square or the tall?

WOODLAWN.

ANSWERS.—1. Yes, the best way is to use the principle of the Heddon plan, which is to get all the worker-brood hatched out before cutting out any combs. Very likely, however, you will be better suited if, instead of driving, you wait till the bees come out of their own accord by way of swarming. For one thing, it's less trouble to have a swarm than to drive them. Another thing is that the bees know

when is the right time when all things are ready for swarming, and you may make a mistake about the best time for driving. If the bees do not swarm by the time most colonies have swarmed, you still have the chance to drive them. At the end of 21 days you can drive out all bees and unite without paying any attention to queens—the bees will settle that matter for themselves.

2. When a prime swarm issues there is a big lot of sealed brood present, and young bees are emerging by the thousand every day, so that when the first young queen is ready to fly there is a strong force of bees ready to go with her. If you can manage to have the larger part of those young bees unite with the swarm, you increase its ability for gathering surplus, and you at the same time lessen the desire for a second swarm. If you put the swarm on the old stand and at once put the old hive in a new place at some distance, all the bees that were out in the field will go back to the old stand, and all the old bees that leave the old hive the next day or so will return to the old stand. This will strengthen the swarm, and at the same time will weaken the old colony so much that it will generally prevent any second swarm. Not in all cases, however, and if we can do anything to throw a still larger number of bees from the old hive into the new, it will be an advantage to do so.

Now, suppose that instead of putting the old hive in a new place at once we set it close beside the swarm. Then two days later we move the old hive to a new place. All the bees will join the swarm that would have done so had we moved the hive on the day of swarming, and in addition to that there will be all the bees that have turned into field-bees in the two days. If we wait until three days after swarming, the number of field-bees will be still larger, and so the number will increase daily for some time. But we must be sure to move the hive before a second swarm issues. Under ordinary circumstances, we are safe to move it a week after the day of swarming. On that day set it in a new place, and all the field-bees will desert it and join the swarm. You can make the matter still more emphatic if you move the hive at a time of day when the young bees are taking a flight, for all of them that are out when the move is made will also join the swarm. For a day or two no nectar will be brought into the removed old hive, and this, together with the depletion in numbers, will so discourage the bees that they will give up all notion of swarming.

It sometimes happens that at the time when a first swarm is ready to issue the weather is so bad that swarming is delayed for two or three days. In that case the second swarm would issue in less time than usual after the first, making it happen that if we wait a week before moving the hive to a new place, there would be a second swarm before that time. So if there has been bad weather just before the time of the prime swarm issuing, it may be well to move the old hive to a new place in six days or even less time after the day of swarming.

3. I don't know enough about them to answer. I had them on trial last year, but the failure of the honey crop left me no wiser than a year before. It will be wise for you to try the two kinds side by side and decide accordingly.

Keeping Bees on Shares.

As there is but very little said in the text-books in regard to leasing or renting bees, I have concluded to ask a question on that subject, not only for my own benefit, but for the benefit of others that may be interested in bees on shares.

Suppose A should lease to B any number of colonies, from 2 to 50, for a term of five years, B to furnish everything—hives, sections, foundation, etc., and do all the work, rear and furnish queens to keep all colonies up to the standard. What rate of interest should A receive annually? And what would be the value of said bees per colony, if Italians in modern hives? Also the value of common bees in common hives? How many colonies of bees should A receive over and above the number least (if any) at the end of five years?

In answering this question the winter losses and taxes along with increase should be taken into consideration. But we will suppose that B works the bees for comb honey and does not care for increase.

INDIANA.

ANSWER.—Very little is said in the bee-books as to bees on shares, for the very good reason that very little can be said that will be of general interest. The one thing that can be said to apply to all cases is that unless everything to

the smallest particular is put down in black and white there will almost certainly be misunderstandings. If the bee-books were to give instruction that would cover all cases, it would make a book of itself. Each case is different from all others, and it is not very likely that a full answer to the present question will be of any use to any other reader, as may be seen to some extent by looking up what is said in the last volume of this Journal as to bee-keeping on shares. See pages 11, 26, 122, 598, 662 and 807. On those pages you will perhaps find more on the subject than is to be found in any of the bee-books, and yet from the nature of the case nothing there said is likely to be of much use to the very next one who desires information on the subject. I regret that I cannot give an explicit answer to every question of the kind, but I think you will see it is impossible.

In the present case the question is less involved than in some others. A has a certain number of colonies from which he wants an annual interest. Plainly, he should have the same interest he would get on the amount of money the bees would sell for, with the bees as the only security for getting back his principal at the end of five years. But that leaves the question still open, for the risk depends much on the locality and the kind of a man B is. The rate of interest is always higher where the security is poor. If the locality is one where it is hard to winter bees in safety, where the majority run out of bees entirely in five years or less, and if B is so little skilled that he doesn't know how to succeed in wintering, there should be a good deal more than the legal rate of interest.

At the end of five years, if A has had his interest annually, he should expect nothing more than his regular interest for that year and his principal back.

The value of bees varies with time and place. It may be three times as much in one place as another. I have no means of knowing what they are worth where A and B live. Turning to page 560 of last year's volume, you will see definite prices given by a man with his mouth full of sobs and his voice full of tears. But those prices may be very different from any A can realize. You can know something definite as to the price of bees of those who advertise them for sale, but that doesn't tell what they are in other places.

Questions on Transferring.

1. I have one colony which is hived in a home-made box, nailed up at both ends. There are two sticks inside crossing each other, and the bees have built the combs everyway. I bored some holes in on top and put on a super, but they didn't do anything above. How can I transfer them into another hive? and what can I do with the comb in the old box?

2. How can I clean the dead bees from the bottom when bottom is nailed? My idea is to take out some frames, scrape an empty space, and brush over the balance of frames towards the clean space. After I get the bottom cleaned I push the frames back in place and put in the ones taken out where they were.

I ought to have a good bee-book so I could learn about bee-keeping.

IOWA.

ANSWERS.—1. If you had put in the super a bait, perhaps the bees would have stored in it. As a bait you can put in a piece of comb. Perhaps you will do as well to leave the hive undisturbed till after the bees swarm, then 21 days later there will be no worker-brood present, and you can transfer according to the directions given in the bee-books. By all means you ought to have a text-book for it will hardly do to take up room here repeating all that you will find in the book. If there are nice, straight combs in the old hive, you can transfer them into the new, and the rest can be melted up.

2. Your way will do, but it is rather slow and troublesome. Take the hive off its stand and set in its place a clean empty hive. Lift the frames out of the old hive and put them in the clean one. Now clean out the old hive and it is ready to replace the next one to be cleaned. If your hives are very heavy and you are not very strong, instead of first setting the clean hive on the old stand, go at it in this way: Set the clean hive near by and lift into it half the frames. Then take the old hive off the stand and put the other in its place, when you can move the rest of the combs. If you try it you will probably like your hives better with the bottoms loose.

The Premiums offered on page 62 are well worth working for. Look at them.

United States Bee-Keepers' Association.

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., E. Whitcomb; Vice-Pres., C. A. Hatch; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GEN'L MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

VOL. 39. MARCH 2, 1899. NO. 9.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

Bees and Honey in Illinois.—In the statistical report of the Illinois State Board of Agriculture for Dec. 1, 1898, which is just received, we note the following:

With the exception of 1891, more honey was produced in 1898 than any previous year. By far the greater part of this was produced in northern Illinois, 423,166 pounds, central Illinois reporting but 128,472 pounds, and southern Illinois, 137,802 pounds.

The Dec. 1 price of honey, 12 cents per pound, is the same as in 1897.

The value of this by-product of the farm in the northern division of the State is \$50,039; in the central division, \$16,837, and in the southern division, \$16,604, giving a total valuation of \$82,480.

There were 62,054 colonies of bees reported to assessors in 1898.

In view of the almost total failure of a surplus honey crop in Illinois last year, the statement made in the first sentence above is amusing, to say the least. The year 1897 was a phenomenal honey-year—honey almost everywhere.

We often wonder who is responsible for the bee and honey statistics that we see made public from time to time. From their apparent unreliability we fear they are "made up" in some machine shop.

Somnambulist and Fire-Water.—Somnambulist, the delightful dreamer down in the Progressive Bee-Keepers' locality, while gently touching up the editor of this journal for mentioning such an out-of-date remedy as whisky for bee-stings, takes the opportunity of saying that he (Somnambulist) is not a temperance fanatic, being a sort of "middle of the road" man, but doesn't want to encourage

in the slightest degree the drinking of fire-water. Which raises some painful questions. Is it possible that the good-hearted Sammy sees so clearly the evils of fire-water that he doesn't want others under its influence, while he is so far under said influence himself that his devious course requires him to get clear out into the middle of the road? Stop it, Sammy. You run risks enough walking in your sleep without the other thing.

Advice to Starters of New Bee-Papers.—Editor Hutchinson, in his February Bee-Keepers' Review, when speaking of the recent improved appearance of some of the bee-papers (notably the American Bee Journal), gives this wholesome advice:

"Let no man start a new bee-journal with any hope of success unless he can make it as neat, at least, as the ones that are now being published. Yes, he must go even further, as the friendship between an old established journal and its readers is very strong, and, to win them away, something considerably better must be offered them."

Actually, some of the new bee-papers that have come to our desk during the past seven years have been simply a disgrace to the printer's art, and quite unworthy of any notice whatever.

But, surely, Mr. Hutchinson would not suggest that a new paper, or any paper, should try to *win away* the subscribers of another or established paper! We have never tried to do that. We would not strive to lessen the number of subscribers of another bee-paper by winning them away, but would simply have them take the American Bee Journal *in addition* to the other paper. We wouldn't advise any bee-keeper to drop the Review for the American Bee Journal, but we would *always urge* the Review subscribers to read our paper also. For after a year's trial, we are certain he would have the American Bee Journal regularly along with the Review, that is, if he were really interested in bee-keeping.

The Door Open for the Union.—In a letter received from Mr. Newman recently, as well as in his report published on page 120, he says that he cannot longer than the present year act as General Manager of the National Bee-Keepers' Union. In the letter referred to, Mr. Newman says:

"I am working harder and harder and spending more strength and vitality every day than accrue in the short period for rest, and therefore I have concluded to curtail some of my labors outside. I am refusing all calls for lecturing, and shall not undertake to manage the affairs of the Bee-Keepers' Union after this year. Fifteen years of my life are all that I can spare in that direction. The almost unanimous vote for me has been *the only tie* that bound me to the work. I did not feel like refusing my many friends to serve them, but now the "physical" demands it, and as I am now close on to 70, I must consider myself a little, and refuse to sacrifice health and strength to labors that can be as well performed by others."

All know that Mr. Newman has done a grand work in the Union during his many years of faithful service, and for the excellent reasons he mentions, he should not be required to wear himself out further in the interest of bee-keepers.

It has been suggested to us (not by Mr. Newman, however), that the members of the Union might now look with favor upon joining its fortunes with the United States Bee-Keepers' Association. It would seem so to us, and if such is their wish, they will find that the door was left wide open for such uniting of forces, should the time come when the Union felt so inclined. The following paragraph, taken from the report of the Buffalo convention in 1897, will further explain about that "open door":

"A Member—Mr. President, as there may sooner or later be an inclination on the part of the members of the

National Bee-Keepers' Union to help put the United States Bee-Keepers' Union [now Association—Ed.] on a more substantial basis, both by their influence and their money. I move that a committee be appointed by the President to devise some plan by which so desirable an object may be accomplished whenever the Advisory Board of the National Bee-Keepers' Union may signify a wish so to do. [Motion adopted, and the Board of Directors appointed as such committee.]"

We republish the foregoing paragraph for the purpose of reminding the Union how nicely the way was left open for them to come into the United States Association, whenever they should so desire. All that is necessary is for the Advisory Board of the Union to express their wish to the Board of Directors of the Association. Mr. G. M. Doolittle is now President of the Union (and we presume chairman of the Advisory Board), and Mr. E. R. Root is chairman of the Board of Directors of the Association.

Now, if the members of the Union's Advisory Board feel that a "wedding" should take place, they could so inform Pres. Doolittle, who would communicate such "wish" to Chairman Root, and likely the contracting parties could be ready to begin "housekeeping" Jan. 1, 1900—the time when Mr. Newman says he must terminate his work as General Manager.

Personally, we had once decided not to speak again of uniting the two organizations in question, but perhaps the time is now at hand when it will be wise to take up the matter and unite under one banner the bee-keepers of this country. We are willing to do what we can to make everybody happy, and if the Board of Directors of the Association shall report, at the next annual meeting, that they had arranged with the Union's Advisory Board to unite the two organizations Jan. 1, 1900, we shall be glad to join in a hearty welcome to the Union's membership, and extend congratulations all around.

Michigan Foul Brood Law.—We understand that a Foul Brood Bill is now before the Michigan legislature, and Editor Hutchinson, of the Bee-Keepers' Review, speaks of it as follows:

"If the legislature thoroughly understands the matter, knows how badly the law is needed, and why it is needed, there is no doubt of its passage. It is the business of the bee-keepers of the State to inform the legislature in regard to the matter.

"If each bee-keeper who reads this will write to his member in the legislature, and fully set forth the reasons why the law ought to be past, it will be past. Don't think that because there is no foul brood in your apiary, nor near you, that there never will be; and the sooner we have this law, and an inspector to look after the matter the better, the less likely is it that it will appear in your yard. Simply write to your member and explain to him the contagious, infectious character of the disease. How it finally destroys an apiary; but that is not the worst of it; bees from other apiaries rob out the depopulated hives, and thus carry home the seeds of the disease to destroy another apiary, and thus it continues to spread from apiary to apiary, unless it is checked. Call his attention to the fact that it is not the bee-keeper alone that suffers but that the fruit-grower and the horticulturist need the bees to fertilize the blossoms, and thus cause them to bring forth fruits in abundance. Don't get up any petitions. Simply write a personal letter to your member, and it will be read and considered, while a petition will simply be tucked away in a pigeon-hole.

"Friends, I beg of you, do not neglect this matter. It is important."

We also would have all of our Michigan subscribers at once write their representatives at Lansing, urging the importance of the foul brood law.

To Get Rid of Laying Workers, Mr. Wilson puts over the colony a queen and some frames of bees and brood, doing this toward evening, and has succeeded in each of the half-dozen cases he tried.—Progressive Bee-Keeper.

MR. N. E. FRANCE, Wisconsin's State inspector of apiaries, is speaking daily upon bee-culture at the farmers' institutes. He expects to be through by March 17. As that is "St. Patrick's Day," we presume he will celebrate then!

MR. WM. STOLLEY, of Hall Co., Nebr., writing us Feb. 17, said:

"After a confinement of 22 days, and part of the time 30 degrees below zero, my bees have had three days sporting in the warm sunshine, and they are now in good trim to stand another severe spell of cold weather."

J. J. G., 1800 Prairie Ave., Chicago, Ill., wants a good, trustworthy man who understands bees thoroughly, and who will be an assistant gardener. The position would be in the White Mountains in New Hampshire, town of Littleton, on an estate of about a thousand acres. The situation is a good one, and a permanent one to the right man. Address as above if you think you can "fill the bill," and want the place.

"PICKINGS FROM OUR NEIGHBORS' FIELDS" is the title of a new department in Gleanings which gives in condensed form items of interest gathered from other bee-periodicals. It is conducted by "Stenog," which is short for W. P. Root, a man not related by blood to the Roots of Gleanings, but one who has had much to do for many years with the fact that Gleanings is typographically so near perfection. He is stenographer and proof-reader, and what he doesn't know about the ins and outs of punctuation and the fine shades of meanings of words is hardly worth knowing. Withal he has a good stock of the sort of humor of which one never tires. He seems to find pretty good "picking" in the American Bee Journal.

MR. THOMAS G. NEWMAN, of San Francisco, Calif., General Manager of the National Bee-Keepers' Union, writing us Feb. 18, said:

"I have seen in the daily papers of the extreme cold and of the storms and blizzards you have been having in the East, for to us Chicago is "East," tho the people in New York think it West, and nearly out of the world. Like all else, the blizzards are but temporary, and soon pass away. The weather here has been cold to us, and very disagreeable much of the time since New Year, but now it is again pleasant and much warmer. We feel the cold here much more at freezing-point than you do in Chicago at zero, because we are not fixt for it, nor used to it, and also on account of the humidity in the atmosphere, and so it always seems to be colder than it really is."

DR. PEIRO, who, as we have reported, visited the Pacific Coast the past summer, speaks thus of the climate of California:

So many wish to know my opinion of California as a climate for persons not in robust health that, with the editor's permission, I am tempted to reply to wholesale enquiries through the American Bee Journal.

For persons in advanced years, to the point of feebleness, or those threatened with a development of serious lung trouble, I would say by all means go to California, and don't stop until you reach Los Angeles or its vicinity. The northern portion of the State as a place of residence for the ailing is from bad to worse generally worse.

I can imagine no climate more delightful than that of Southern California. But you will do best first to go there, say for a year, and see how you personally like it before you "pull up stakes" at the old home for good.

One thing you must also consider—while the climate is excellent it is a poor place for a working-man without capital to depend upon earning a living. You may do so, but it is best to rely upon a well-filled pocket-book.

DR. PEIRO.

To Prevent a Swarm Scattering into other hives, simply sprinkle the bees with a little water whenever you dump them off the branch on which they have clustered; then they will not take wing, but march straight for the hive in front of them.—F. L. Thompson, in *Progressive Bee-Keeper*.

Getting Section Honey and Extracted from a colony at the same time, is characterized by G. M. Doolittle in the *Progressive Bee-Keeper* as a *myth*. So long as there is any room in the extracting-combs, bees will build no comb in sections, even if the extracting-combs are farther than the sections from the brood-nest.

Getting Light Honey from the Wax-Extractor.—Ordinarily the honey that comes from cappings thrown in the wax-extractor is injured and darkened by the great heat required to melt the wax. Rambler finds he can get the honey in good condition by a mild heat long continued. This is secured in a cloudy day, and in a bright sun he makes his own clouds by putting a gunny-sack or something of the kind a few inches above the glass.—Gleanings.

A Point for Large Hives is made by Adrian Getaz in *Gleanings*, who insists that it is not enough that colonies are strong to overflowing when the harvest comes, but says he gets best results from those that are strong *before* this time, even if no stronger than others when the harvest begins. He thinks that when a colony merely fills up with bees ready for the opening of the harvest, that the workers are not old enough for best results. Practically, the colonies must be strong the preceding fall.

Bee-Keeping in Cuba seems to be a live topic nowadays. W. W. Somerford talks about it in *Gleanings*. He thinks bell-flower or campanilla honey is finer than basswood, and one who eats it will want more. He tells of 700 gallons pure sugar-cane honey being extracted and unsalable, which the bees gathered the first year of the war from burnt cane-fields. He thinks that competition from Cuban honey need not be greatly feared, as Cuba is not so very large, and not more than half of it will do to keep bees on at all, except as a side-issue.

Practice Better than Theory. What I have done, and the result, is of far more importance to the world than what I want and why. In other words, if more of our writers would wait about telling us their theories till after they had practiced them for a few years, and then tell us how they work, and their success, less chaff would appear in our newspapers, and the fraternity be saved much by not being led to try so many will-o'-the-wisp things, which result in a long "chase" after nothing.—G. M. Doolittle, in the *Progressive Bee-Keeper*.

Some Interesting Apicultural Figures, in the *American Bee-Keeper*, are given by G. M. Doolittle. He began bee-keeping in 1869, paying 10 cents each for 6-pound boxes. Got two boxes filled and ate the honey. The next year he sold at 25 cents a pound, boxes costing \$16.66 for each 1,000 pounds of honey. In 1872 or 1873, 2-pound sections came in, costing \$30 a thousand in the flat, or \$40 ready for use. Sold honey in 1874 for 28½ cents, or 27 cents after taking out cost of sections in flat. These sections fell to \$25, \$18, \$15, \$12, \$10, 88, and \$7. To-day the finest 1-pound sections are \$3, and if honey had fallen in the same proportion, section honey would to-day bring 6 cents a pound.

Does the 8-Frame Hive Accommodate the Average Queen? In answer to this question, C. P. Dadant says in *Gleanings*

"Emphatically I will say no. Neither do I think that the bee-keeper who makes any tests at all, no matter who he is or where he is, would answer the question in any other way. My experience is that about 1/3 of the queens are crowded in a 10-frame brood-chamber, and that not over one-tenth of the colonies can be sufficiently accommodated

with breeding-room in an 8-frame hive; while perhaps only two or three percent of the healthy queens would find this hive too large.

"Perhaps many people will disagree with me, who have never used anything larger than an 8-frame hive, because they judge of the possible strength of a colony by the experience that one may get with such a hive. I beg leave to say that it is next to impossible to judge fairly of this question without first giving a trial to large brood-chambers the year round. It is useless to expect as populous a colony for either spring, summer, or winter, on an average, in a small hive, as in a large one. One might as well expect as large a colt from a pony as from a Norman mare. A greater cluster, a larger space, and a greater amount of stores are bound to produce, with a queen to match, a more satisfactory colony."

Shall Sections be Scraped?—Editor Holtermann, of the *Canadian Bee Journal*, does not take kindly to the idea that it is better to have sections daubed with propolis so people will think the honey genuine. He says:

"The above reminds me of an incident when out at Farmers' Institute work some years ago. The member of the Government deputation with me was very partial to milk, of which very little, even for tea and coffee, had been upon the table for some time (we were in a newer and colder part of the Province). One day for dinner a jug of milk appeared upon the table. I took half a glass and began sipping it. It tasted so strong of the stable I suggested to my colleague there was no mistake about it; this was genuine cow's milk. He filled his glass promptly and downed half of it before he struck the flavor. It was cow. We do not require to have our honey product in a crude condition to enable an intelligent public to understand it is genuine. It is just as absurd to call for propolized and travel-stained honey as it is to call for hair in butter."

Sweet Clover—Melilotus.—This plant closely resembles Alfalfa, but makes a much larger and coarser growth, and is especially adapted to lime soils. It will make a good growth on any lime soil, even on the white barren lime-hills, where the land is so poor that no other plant will live. Melilotus is of little or no value on the red clay or sandy soils which contain little lime. In this latitude it is a biennial plant, making only a moderate growth the first year, but an excellent growth the second. This plant comes from seed the first year and from roots the second, and will then continue to re-seed itself for years without interference. The seed may be sown late in August or in February, at the rate of 1/2 bushel per acre, as directed for *Lespedeza*.

Melilotus, in either the cured or green state, is not generally liked by animals unaccustomed to it at first, but they soon learn to relish it, and it is very nutritious either in the green or cured state. Melilotus starts into growth early in the spring when other green forage is scarce, and stock learn to like it quickly. This plant not only furnishes a large amount of grazing, but has few equals as a soil-improver. —Mississippi Experiment Station Bulletin.

Tar Odor a Cure for Foul Brood.—Loyalstone says in *Australian Bee-Bulletin*:

"I got some foundation, wrapt a piece of cheese-cloth over it, then I got a box of thin wood, placed two pieces of tarred felt in the bottom of it, put the foundation in cloth on top of this. Then put two more pieces of tarred felt on top. Put this in a warm place for three weeks, when the foundation had inhaled the tar it smelt very strong. I then hived two swarms bad with foul brood in a fresh hive with starters made of this foundation, and hived two other swarms bad with foul brood in a fresh hive with starters of ordinary foundation, with this result: The two swarms hived on tar-smelling foundation showed no sign of foul brood. The other two hived on ordinary foundation were again attacked with foul brood. So again I experimented. The worst of these two I hived in a fresh hive with starters of tar-smelling foundation. The other I hived in a fresh hive with ordinary foundation. Again the hive with anti-foul-brood foundation showed no signs of foul brood, whereas the other one was infected. The last I transferred into a fresh hive with anti-foul-brood foundation, and it showed no signs of foul brood. I then got a lot of thin cakes of wax and put in a box in a warm place surrounded with tarred felt, and in six weeks the smell of the tar was so strong in the wax that you could not boil it out. The more the wax was boiled the stronger was the smell. Make this wax into foundation and foul brood will not trouble you. It has not in the many cases I have tried.

Root's Column

HAND-HOLE CLEATS FOR HIVES.

We have finally got them perfected—or at least so they suit us, and now offer them in all our Dovetailed hive combinations. They are nothing more nor less than short pieces of moulding beveled at each end, and nailed so as

to come directly over the top edges of the hand-holes, as shown above. The following illustrations show a little more of the detail.

Perhaps the question may be asked why the hand-hole cleat alone would not be sufficient. It is much more convenient than the hand-hole alone; and the two in combination are far better than either alone. When one tries to lift a 50-pound hive by hand-holes, his fingers can get a

grip only at the mere tips, on a sharp edge, as at D. Such a hold is a severe strain on, if not painful to, the ends of the fingers; and one does not feel that he cares to lift very many hives in this way; but if he can get the hold of the weight on the middle joints of the fingers, as at A, and on a rounding edge, he can lift all that his back will stand.

We sell these cleats separately when called for, at 75 cents per 100, or \$6.00 per 1,000. They can be attached to hives already in use; and where they are to be moved to out-yards, or handled very much, these cleats are a great convenience, and worth many times their cost.

Dr. Miller wants his cleats to go clear across the hive. If there are those who prefer to have them so, we can supply their hives with such, but the price of the cleats will be twice as much as for the short ones, and will be supplied only from the factory, as our dealers will keep only regular goods.

The A. I. Root Company
MEDINA, OHIO.

GENERAL ITEMS

Bee-Keeping in Arizona.

Last season I ran my apiary for extracted honey, and colonies averaged about 80 lbs. My neighbor, Mr. Glasscock, had 140 colonies, and they averaged 40 pounds of comb honey, which is rather a poor crop here. The alfalfa was a failure, but the old reliable mesquite never fails here, and we are always sure of a fair crop; it yields a milky white honey, much like the alfalfa.

The prospects are good for next season, as there has been plenty of snow and rain in the mountains, and bees are in fine condition at the present writing.

All the practical bee-keepers here use the Langstroth hive, while a great many use box and old hollow log, and call the queen-bee a "king."

The first honey-bees were kept here about 16 years ago, which were shipped from California. There were 10 colonies brought on an ox-wagon. Now the timber and rocks in the mountains are full of bees. There is a fly here that ruins the alfalfa honey one year out of three. It seems to suck the bloom to death.

W. D. JEFFERSON,
Graham Co., Ariz., Jan. 3.

The Bee Journal Helpt Him.

I commenced with one colony in the spring of 1895. I now have 22 colonies packed on the summer stands. I think they are in good condition. I owe my success so far to a careful reading of the American Bee Journal.

D. W. WILL,
Somerset Co., Pa., Jan. 16.

Report for 1898.

In the spring of 1898 I sold five colonies, and had 54 left, which increased to 91, by natural swarming, and 1500 pounds of comb honey. I peddled it out at 10 cents a pound except a little in spring that was not so good, which I sold at 8 1/2 cents.

A. R. YANDELL,
Indian Territory, Jan. 17.

Bees Have Frequent Flights.

My bees have flown out more or less nearly every day this month. They are doing all right so far as I know. I have 18 colonies in the cellar that can't enjoy this nice weather to fly out.

NOAH MILLER,
Iowa Co., Iowa, Jan. 24.

Something About Bee-Stings.

Seeing several articles in regard to bee-stings, I may have a word also. From the action of the poison it seems to be of the same nature as a snake-bite, and no doubt if the same or equal amount of the poison were forced into the circulation its effect would prove equally fatal. I used to be very susceptible to the effects of bee-stings, but after a continued interview of the business end of bees for about 30 years it does not affect me so seriously. But there are several things to do in case a sting is received, and several not to do, i.e., don't attempt to pull out the sting the first thing, but leave it right where the bee put it. The reason for this is, a bee's sting is barbed like a fish-hook, and the sac containing the poison is always left with the sting; any attempt to pull it out only forces more poison into the wound. Don't stand near the hive any longer than necessary after being stung, but move back gently a few feet, as the smell may anger more of the bees. Don't make any quick demonstrations, but move gently and quietly out of the immediate vicinity. Before you go among the bees provide yourself with a little salt where you can get it handy, and a small

Earliest Good Tomato. Absolutely first of 200 kinds. Medium in size, slightly wrinkled, but of first quality and first in the market. Large package 10 cts., only, with our complete 1899 catalogue, "A MIRROR OF AMERICAN HORTICULTURE." It tells the whole story of the garden, lawn and farm. The American Poultry Journal

325 Dearborn Street, Chicago, Ill.

A Journal that is over a quarter of a century old and is still growing must possess intrinsic merit of its own, and its field must be a valuable one. Such is the American Poultry Journal.

50 cents a Year. Mention the Bee Journal.

The Rural Californian

Tells all about Bees in California. The yields and Price of Honey; the Pasturage and Nectar-Producing Plants; the Bee-Ranches and how they are conducted. In fact the entire field is fully covered by an expert bee-man. Besides this the paper also tells you all about California Agriculture and Horticulture. \$1.00 per year; 6 months, 50 cents. Sample copies, 10 cents.

THE RURAL CALIFORNIAN,
218 North Main Street, - LOS ANGELES, CAL.
Please mention Bee Journal when writing.

(ounce) vial of the best whisky; immediately swallow about one teaspoonful and lay a little salt on the sting and wet it with the whisky. You will, if not a drinking person (and no bee-keeper should be) feel the poison going into the circulation from the wound and the whisky from the stomach. This is the only remedy I have ever found, if I except the exudations from the ear, i.e. ear-wax, which will stop the pain of a sting *instantly*, but it is not always attainable.

After the salt and whisky are applied, let the sting dry up, and then remove it with a knife. But you can go right back amongst the bees without fear of their smelling or being angered, as the whisky and salt kills the smell as soon as applied.

Garland Co., Ark. J. H. HERMANC.

[We fear that if some bee-keepers should take a swallow of whisky every time they are stung they wouldn't be able to do much with bees or anything else. We would much prefer to endure the pain of the sting than to swallow the whisky. We are too old to begin to take whisky, and wish the vile stuff had never been invented. The world would be better off without it.—EDITOR.]

Almost Discouraged.

I have become almost discouraged in the bee-business, with three years of failure. Formerly this was considered one of the best locations in central New York. Last spring my 105 colonies came through without any loss, and in good condition. I was looking for early swarms, and tho the spring was cold and wet my bees increased and filled the hives with bees, but refused to swarm, and they continued throughout the season. I had no increase, and but about 500 pounds of poor honey in the supers, with my bees in fair shape for the winter, that is, with plenty of honey and bees.

One of my neighbors sprayed his fruit-trees last spring, and I claim that it killed the bees for he did it while the trees were in full bloom.

H. Root. Cortland Co., N. Y.

Wintering and a Report.

I am trying wintering bees again in my frame building. The four colonies came out all right last spring, and I increased to 11 and got 300 pounds of extracted and comb honey. I think they have plenty to winter on also, and a few frames for spring, if needed.

Last winter I set the hives in a row, and covered them all around below as above with a foot or more of oats chaff, leaving a spout of two or three inches through the chaff to the open space inside, to give them air. I likewise gave them two one-inch holes through the honey-boards on top, covering them with wire-cloth and sacking to keep out the dust.

This year I have built them three deep, and covered them in chaff in the same way, and now wait results.

If all is favorable in the spring I would like to double my number of colonies, and do it by dividing. They were put in the first week of November, and we do not look for them getting a flight before the first or middle of April or later. I think the dividing plan suits my time and idea better than watching for swarms.

R. McCRAIDIE, Norman Co., Minn., Feb. 6.

Some Good Southern Honey.

Having seen so many expressions in the American Bee Journal as to the poor quality of Southern honey, I send a sample, under separate cover, of gallberry honey, to get your opinion.

About 18 months ago I sent a sample of the poorest honey I produced that year (1897) and I was surprised when you said it was "better than the usual samples of

Southern honey received," so please let me know what you think of this.

The past season was quite satisfactory here. I had 500 pounds of as nicely put up white comb honey as I ever saw (and I have lived in Iowa, where we had white clover); also 200 pounds of extracted, from 20 colonies, spring count, and increase to 22. I have sold it all at good prices, and could have disposed of as much more had I had it.

I expect to double the number of colonies this winter (by purchase), and hope to do even better this year.

ERNEST W. HALSTEAD,
Jackson Co., Miss., Jan. 17.

[The sample of honey arrived in good order, and is most excellent in flavor and body. It would suit us almost as well as the best alfalfa. No wonder it sold at good prices, and people were looking for more.—
EDITOR.]

Bees are Quiet.

Bees are very quiet. I have 27 colonies. I did not get much from them last season.
G. H. LAWRENCE,
Juneau Co., Wis., Feb. 5.

Results of the Season of 1898.

Bees did not do a very big business here last season. I had 16 colonies in the spring, increase to 24, and got 700 pounds of comb honey. They are in good shape now, and wintering well. I will try the Golden method next summer. **H. D. STEPHAN,**
Wabasha Co., Minn., Feb. 7.

Fire in a House-Apiary.

I had an experience in rendering wax which for speed beats anything I have ever seen, but I cannot say that I care to use it. I keep my bees in a house-apiary; the bees are on the south side, with supers, extra hives, tools, etc., on the north side. My extracting-frames and combs of honey I keep in a cupboard. Last night, from some unknown cause, the place caught fire. I live in the village, and the fire department was soon on hand, and gave the best of service. Everything on the north side was destroyed, but my bees are all safe and sound. Some of the hives are scorched, but a little paint will remedy that.

J. M. DONALDSON,
Worcester Co., Mass., Jan. 27.

Poor Year for Bees.

We started in last year with 25 colonies, and saved 16 swarms, 5 of which died, leaving us with 35 colonies.

Last year was a poor one for bees in this locality. We got only 309 sections of good comb honey. I have been taking the American Bee Journal for nearly a year now, and have found it very instructive and useful. **W. Z. FONTAINE,**
Davidson Co., Tenn.

A Maryland Bee-Keeper's Report.

We are now having very nice weather, yesterday the thermometer indicating 70 degrees, and the bees were taking a good flight and doing a little house-cleaning, getting ready for spring. My bees are on the summer stands with lots of honey. I have them protected on the West with boards and fodder, and face them to the East. But we had some very cold weather about the holidays, but only for a few days at a time. New year's night, or the morning of Jan. 2, the temperature was down to 14 degrees below zero. It is feared by the peach-growers in the mountain belt that it has frozen the peaches, but lucky for the bees, they pulled through.

The honey crop was short last year—too wet and cold in the spring. I could not complain much, as I had an average of about 30 pounds per colony. I had a field

Bees Wanted FINE LAND

At \$5.00 per acre to trade for bees.

HARRY McCARTER,
Dodge City, Kans.

ALBINO QUEENS If you want the most prolific Queens—if you want the gentlest Bees—if you want the best honey-gatherers you ever saw—try my Albinos. Untested Queens in April, \$1.00; Tested, \$1.50.
J. D. GIVENS, LISBON, TEX.

Those Wonderful Dogs.

We received the Scotch Collie Male Pup all right and am very much pleased with him. We think you made a good selection.—Horton Longyear, Lansing, Mich., Feb. 9, 1899.

Our Scotch Collie male pup arrived in splendid condition. He suits Mrs. B. splendid, and we think he will make a fine dog.—Rev. D. M. Buchanan, Manch Chunk, Pa., Feb. 7, 1899.

The Scotch Collie male pup which we received a week ago is doing first-rate and seems very intelligent. We are well pleased.—W. J. Snyder, Mowenaqua, Ill., Feb. 3, 1899.

The pair of Scotch Collie, male pups received last week are very nice.—A. F. Carlson, Renovo, Pa., Feb. 9, 1899.

I received the three Scotch Collie pups last week all right. I am well satisfied with them. They are the pets of the whole family.—Henry McConnell, Arnot, Pa., Feb. 2.

The Scotch Collie pup arrived all right. He is as fine a little fellow as I ever saw. Think he will be grand as he grows older. In fact I am more than pleased with him.—Mrs. J. H. Ellingwood, E. Lexington, Mass., Feb. 2, 1899.

For particulars and prices, address **POTTS BROS.,** box P, Parkersburg, Pa.

No. 191. Fancy Body Top Buggy; is complete with side lamps, fenders, side curtains, storm apron and shafts. Price \$40, as good as dealers sell for \$50. Write at once for Illustrated Catalogue—FREE.

BE YOUR OWN AGENT

and Save Money. Every time you buy an article from an agent or dealer you must pay him a liberal commission in addition to the actual value of the article. In many cases this places an article beyond your reach.

WE HAVE NO AGENTS but sell you vehicles and harness direct from our factory at wholesale prices.

We are the largest manufacturers of carriages and harness in the world selling to the consumer exclusively. We make 170 styles of vehicles, surreys, as low as \$50, and 65 styles of harness. Remember that we ship our goods anywhere for examination and guarantee safe delivery.

Page & Lyon Mfg. Co.

NEW LONDON, WIS.,

Operates two Sawmills that cut, annually, eight million feet of lumber, thus securing the best lumber at the lowest price for the manufacture of... **Bee-Keepers' Supplies...**

They have also one of the LARGEST FACTORIES and the latest and most improved machinery for the manufacture of Bee-Hives, Sections, &c., that there is in the State. The material is cut from patterns, by machinery, and is absolutely accurate. For Sections, the clearest and whitest Basswood is used, and they are polished on both sides. Nearness to Pine and Basswood forests, and possession of mills and factory equipt with best machinery, all combine to enable this firm to furnish the BEST GOODS AT THE LOWEST PRICES.

Send for Circular and see the prices on a full line of Supplies.

Please mention Bee Journal when writing.

of 20 acres of sapling or peavine clover for my bees to gather from, and they made good use of it, too. I got a little over 1,000 pounds of nice honey, but the sections were not filled very heavy. I shipped 600 pounds (nearly 700 sections) to Washington, D. C., and it netted me little over 12 cents per section; and the other 400 pounds we will eat. We have seven in the family and all big honey-eaters.

I purchast a few colonies Jan. 21, for from 25 to 50 cents each. Some were in old nail kegs almost falling to pieces, and some in the old Stoddard hive, patented in 1848. I purchast them along the mountain near McClean's Lookout, during the battle of South Mountain and Antietam.

L. A. HAMMOND.

Washington Co., Md., Jan. 23.

Bees Did Well Last Year.

I have some 20 colonies run for extracting. We did well last year, getting more honey than we ever got before. I can sell all we get. I have been a bee-keeper all my life, but only knew bees sting and gather honey until three years ago, since when I have read the American Bee Journal and other bee-literature. I am 60 years old, and am an invalid, yet able to attend to a limited number of colonies of bees.

W. A. THOMPSON, SR.

Franklin Co., Va.

Wintering on the Summer Stands.

My bees are wintering well on the summer stands. I have some in chaff hives. All are doing well so far. They have had three good flights, but I never saw so many dead bees in wintering as this year.

HENRY LOHAUS.

Platte Co., Nebr., Jan. 28.

Improvements in Wax-Extractors.

I have been giving the solar wax-extractor some study, and anything that appears in the bee-papers upon that subject immediately commands my attention.

Mr. W. L. Porter's paper and the discussion that followed at the recent meeting of the Colorado State Bee-Keepers' Association, was of interest, and among other things I note what is said about the material that is put into the extractor, sliding on the pan and damming in a mass at the lower end. Persons who have access to Gleanings in Bee-Culture for Jan. 15, will note an illustration and the efforts I have been making to overcome some of the objections in the ordinary solar wax-extractor.

Instead of making the delivery at the end I make it at the side. The pan is made of tin, and can be adjusted in various positions from nearly horizontal to quite an incline. Upon the delivery edge I have a dam or strainer of coarse-mesh wire-cloth; there is no damming of refuse in this extractor, and the wax is rendered quite rapidly. I think a can four feet in length and 20 inches in width is sufficiently large to render all the cappings and scraps from a large apiary.

My primary idea for a side delivery was to allow the quick exit of the honey usually mixt with the cappings, and to save the honey from becoming darkened by heat; this is greatly promoted by shading the extractor while the honey is being rendered, and then giving the residue the full rays of the sun.

This extractor was made in the backwoods of Siskiyou Co., Calif. I have plans now for another for this southern country, which will be a little more finish in appearance, and with a wax-caking attachment.

I hope the Colorado friends will have their extractor illustrated, for it is only by comparing notes that we can improve and approach perfection.

J. H. MARTIN.

Los Angeles Co., Calif.

[We should be pleased to give an illustration of both Mr. Martin's and the Colorado extractor, if they will please send us either drawings or photographs of them.—Ed.]

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Feb. 16.—This month trade has been of small volume in comb honey, due perhaps to the extreme cold that has made transportation dangerous, we now look for a better movement; yet the season is drawing to a close, as after the middle of March there is practically none sold until the new harvest is ready.

Fancy grade of white comb, 13c; travel stained and light amber, 11c@12c; amber and dark, 8c@10c; candied and mixt colors, 6c@7c. Extracted, white, 6c@7c; amber, 5c@6c. Beeswax, 27c@28c. R. A. BURNETT & CO.

DETROIT, Jan. 2.—No change in supply of honey as to quality, but prices are somewhat lower than last quotations, viz: Fancy white, 13c; No. 1, 12c@12½c; fancy dark and amber, 9c@11c. Extracted, white, 6c@7c; dark, 5c@5½c. Beeswax, 25c@26c. M. H. HUNT.

INDIANAPOLIS, Jan. 4.—Fancy white comb, 12c@12½c; No. 1, 10c@11c. Demand fairly good, Dark comb honey is being offered at 8c@9c with almost no demand. Clover and basswood extracted, 6½c@7c. Beeswax, 26c@28c. WALTER S. POWDER.

NEW YORK, Jan. 26.—Fancy white, 12c; No. 1 white, 10c@11c; amber, 9c; buckwheat and dark, 7c. Extracted in good demand at unchanged prices. Beeswax rather quiet 27c@28c.

Trade in comb honey is quiet. White is pretty well cleaned up, but there is a large stock of buckwheat, amber and mixt, having accumulated of late, and in order to sell in quantity lots it is necessary to shade quotations. HILDRETH BROS. & SEGELKEN.

SAN FRANCISCO, Feb. 8.—White comb, 9½c@10½c; amber, 7½c@9c. Extracted, white, 7c@7½c; light amber, 6½c@6½c. Beeswax, 24c@27c.

Market is not favorable to buyers, more especially for desirable extracted stocks, of which are decidedly light. Comb is in moderate supply, and has to depend almost wholly on local custom for an outlet. Quotable rates remain as previously given.

BOSTON, Feb. 8.—The demand for comb honey is very light, with full stock on hand. We quote our market: Fancy white, 13c@14c; A No. 1, 12c; No. 1, 11c@12c; light amber, 9c@10c. No demand for buckwheat. Extracted, white Northern stock, 7c@8c. Beeswax quiet at 27c@28c. BLAKE, SCOTT & LEE.

KANSAS CITY, Jan. 25.—Fancy white comb, 13c; No. 1, 12c; amber, 11c; dark, 10c. Extracted white, 6c; amber, 5c; dark, 4½c. Beeswax, 25c. C. C. CLEMENS & CO.

BUFFALO, Feb. 24.—Closely cleaned up on fancy one-pound combs; such kinds move brisk to-day at about 12 cents. Other grades have cleaned up mostly, but few remaining which are selling at 9c down to 7c. Extracted honey not much used here; stray lots 5c@6c. Fancy pure beeswax, 30c@33c; common, 22c@28c. BATTERSON & CO.

CLEVELAND, Jan. 2.—Fancy white, 13c@14c; No. 1 white, 12c@13c; A No. 1 amber, 10c@11c; No. 2 amber, 9c@10c; buckwheat, 8c. Extracted, white, 7c; amber, 6c; buckwheat, 5c. A. B. WILLIAMS & CO.

MILWAUKEE, Jan. 9.—Fancy 1-lb. sections, 12½c@14c; A No. 1, 12c@12½c; No. 1, 11c@12c; dark or amber, 8c@11c. Extracted, in barrels, kegs and pails, 6½c@7½c; dark, 5c@5½c. Beeswax, 25c@27c.

The condition of the market is favorable for shipments of honey, especially of best grades, which are in small supply. The sales are moderate, but we are expecting an increased demand and good trade this spring. A. V. BISHOP & CO.

SECOND-HAND Sixty-Pound Cans For Sale Cheap.

We have another lot of about 300 second-hand 60-pound Cans, two in a case, that we offer, while they last, in lots of five or more cases (10 cans) at 40 cents a case, f.o.b. Chicago. They are in good condition. Better order at once if you want some of them. Address, GEORGE W. YORK & COMPANY, 118 Michigan St., Chicago, Ill.

CONTRIBUTED ARTICLES

Influence of Locality on Bee-Management.

BY ADRIAN GETAZ.

THIS title sounds somewhat like a joke. A few years ago, when something happened that was not fully understood, it was customary to attribute it to the "strain of bees;" later on, the accusation was made against the "locality." Nevertheless, it is true that the locality, or rather the climate, the length and character of the honey-flow, and several other circumstances, including the methods of management and the awkwardness of the keeper, play an important part in the results obtained.

WINTERING BEES.

Among the periodical articles that appear regularly every year or so in the different bee-papers, is one by Mr. Doolittle, to the effect that the bees dying in small groups outside of the main cluster, during the winter, are old bees which went off for the purpose of dying. This statement has often been denied, and many have said that the bees thus found were those unable to reach the main cluster in time, and simply died of cold.

My own experience is in accordance with this last point of view. I frequently find small clusters of bees between the outside combs, that have evidently died of cold because the main cluster beyond has receded and thus withdrawn its warmth. Or, sometimes they have eaten what honey was around them, and on account of a too low temperature failed to go around the combs and reach another part of the cluster or of the honey.

Mr. Doolittle is a very careful observer, and his statements are always correct, or practically so. In this case the difference of opinion can very easily be accounted for. Doolittle winters his bees in a cellar, or rather a repository, in which the temperature remains at about 40 degrees during the whole winter. The inside of the hives outside of the cluster must be higher by a few degrees. Under such circumstances (shall I say "locality?") I think those of the bees that may be separated from the main cluster, or get out of stores, can crawl around the combs and reach a better place.

In my "locality" the case is altogether different. I winter my bees outside. The climate during the winter is very variable. To-day the bees may fly freely. A cold wave comes, and in 24 or 36 hours the mercury may drop away below the freezing-point, if not below zero. What are the consequences? During the warm days the cluster of bees expands considerably, they fly out freely, and when the night comes they occupy the spaces between several combs. When the cold comes, the different parts of the cluster contract, and those numerous enough can keep

warm easily, but the smaller portions between the outside combs cannot, and before long the weather is too cold to permit them to go around the combs and rejoin the main cluster. I think that some passage-ways through the combs would help them greatly in such cases, and I am going this year to try some arrangement of that sort.

STIMULATIVE FEEDING OF BEES.

This is another of Mr. Doolittle's periodical subjects. He objects to it. And let me say here that on this point Doolittle has often been misunderstood, or misquoted. Many times it has been said that Doolittle is not in favor of feeding. That's wrong. Doolittle says positively that unless there is plenty of stores in the hive, the bees will not breed freely, and if there is not plenty all the time, feeding

Adrian Getaz.

must be done. He calls plenty the equivalent of two combs of honey.

What Mr. Doolittle objects to is the feeding of a small quantity of honey every day, or every night for the purpose of stimulating brood-rearing. On the other hand, quite a number of our best honey-producers practice successfully that kind of feeding.

This is a question not of "locality" but of manage-

ment. Mr. Doolittle practices what is called "spreading the brood-nest." That is, every few days he goes over his colonies, takes the center combs, which are full of brood, to the outside, and those that have but little brood he puts in the center. In doing this, he compels his bees to rear all the brood that they can take care of. Under such circumstances, stimulative feeding could not add anything to the amount of brood reared.

The others obtain the same result by stimulative feeding, and if they were to add brood-spreading to it, they would probably find no advantage in it. It is simply a choice between the two methods.

SPACE FOR QUEENS.

Some time ago Mr. Dadant said that one reason for having a pretty good sized brood-nest is, that if the queen has only a few combs she may have to go over a good deal to hunt up the empty cells, and therefore lose quite an amount of time, while with plenty of comb space there will always be some cells within reach. To which Mr. Doolittle retorted that *his* queens didn't have to hunt up space to lay in. Whether their queens spend much time in hunting up space or not is evidently a matter of "guess-work." As both "guessers" are experienced bee-keepers, their "guesses" must be pretty near the truth. And here Doolittle's brood-spreading explains the difference in their opinions, for by it he gives his queens plenty of space to lay, and at the best place, that is, the center of the brood-nest.

THE TWO-STORY BROOD-NEST.

On commenting on the subject of a two-story brood-nest, Mr. Hutchinson suggests that it might be as well to add one or two supers to the first story instead of a second brood-nest story. This is unquestionably a question of "locality." If I understand rightly, E. R. Root wants to add the second story at a time when the honey gathered is dark and comes in moderate quantity, and replace it by supers only when the more abundant flow of white honey comes, preferring to turn the dark honey into bees. These bees are to gather the white honey which follows.

If the honey-flow is of short duration, I should think better to put on supers at once than to rear bees that would be too late to help during the flow. In "my locality" the flow is never very heavy, and is very irregular, and the only way I can obtain some surplus is to keep the colonies very strong throughout the whole season, so they can take advantage of whatever flow may come at any time.

Knox Co., Tenn.

Securing a Foul Brood Law in Illinois.

BY J. M. HAMBAUGH.

I AM really gratified to see our old friends in "Suckerdom" taking such aggressive and bold steps for the obtaining of a foul brood law in that State.

Mr. Stone, as you know, is an old "wheelhorse," and always ready for battle, and many a tilt have we had in defense of the bee-keepers' interests in the days of "Auld Lang Syne."

As for Mr. Dadant, every blow that he administers is a "sledge-hammer blow," and now that he has appeared above board in the aggressive vindication of the foul brood law, we shall expect good results to emanate therefrom. And now, fellow bee-keepers of my native State, wouldn't it be a grand idea for you to bring proper influences to bear that would elevate Mr. Dadant to the dignity of a "Member of the Illinois General Assembly?" You would have a powerful exponent of your rights and privileges in the law-making machinery of the State. With such a member (if he is a Frenchman) to entrust to his keeping such a measure as the foul brood law as now proposed, you could rest assured that his keen foresight would quickly map out the ways and means by which to bring about the necessary votes and support of the Bill to enact it into law. He would reason like this:

Never can this proposed measure be gotten upon the statute books without the necessary number of members in both branches of the legislature to approve of the Bill, and the governor to sign it; and in order, first, to bring this about, the members must first be convinced that there is some true merits in the Bill.

Secondly, that it is really and absolutely wanted by their constituency.

Thirdly, that it will ultimately achieve the ends at which it is aimed.

And now, in order to bring this about, he must bear in mind the old adage, "Eternal vigilance is the price of success." He must know also that there is work to do. He must not only have a strong representative lobby before the committees of the two houses, but from all parts of the State must come strong appeals from the constituent bee-keepers, to the various members composing these committees, to vote favorably on the measure. The more cudgels that can be wielded over the heads of members by their constituents, the better; and remember, that a favorable consideration of a Bill before the committee is equivalent to one-half the battle.

After the Bill is favorably considered, see after the measure closely that it is not pushed to the rear and "pigeon-holed," but promptly brought to its place on the calendar.

And now is the time for the importuning of the members for a favorable consideration, with all the force that can be brought to bear, from every bee-keeper that can be mustered into service, in the way of writing to their representatives and senators, and sending petitions, etc., in behalf of the measure, and see to it that a strong, vigilant vanguard is ever on deck to throttle opposition in whatever way it may present itself, by counter active arguments and work from its advocates and the opponents' constituency.

And now, fellow bee-keepers, if you are in earnest and need the law, it is your duty to work for the same. I appreciate Mr. Stone's energy and grit. I know him of old, but it is not within the province of any one man to convince a whole legislative body of men to enact a law, where there is no approval at his back from the people who are directly interested, and a legislator is quick to note this point.

Now, as neither Mr. Dadant nor Mr. Stone are members of that "disreputable" body, you must secure the services of the next best man you can get, and let me beg of you, don't get one to introduce the Bill and then sit back and let the Bill take care of itself, as was done with a former foul brood bill, which I have a recollection of. It was a case of "The father of the Bill didn't father it."

San Diego Co., Calif.

[No doubt Mr. Hambaugh's advice is most excellent, whether it be Illinois, Michigan, or any other State that is attempting to secure a foul brood law. Mr. H. ought to know, for he was at one time a member of the Illinois legislature.- EDITOR.]

A Prayer for the Night-Time.

BY HON. EUGENE SECOR.

O cover my senses, thou Giver of sleep,
With the night of Forgetfulness over;
May slumber be restful, and trustful, and deep,
Till daylight return, daily rover.

The morning will break on a world of unrest;
For me there'll be duty or labor;
May the strength which I gather while Day's in the West,
Be spent as for God and my neighbor.

Forest City, Iowa.

No. 2.—Doolittle's Talk on Bees at a Farmer's Institute in New York State.

BY REPORTER.

[Continued from page 133.]

HE next spoke on honey, told how it was of two kinds, comb and extracted. How extracted was different from the "strained" honey of former times, explaining fully all about how extracting was done, and told in a story-like way how his old mother used to strain honey 50 years ago. Then how honey was the purest sweet in the world, most easily digested, etc., and yet, strange to say, hardly one person in three, as nearly as could be ascertained, ever tasted honey.

He next told how those eating honey never stooped to think of the very nice mechanism of the comb, which is so thin that it takes nearly or quite a thousand thicknesses of it to make an inch; how the six sides of one cell formed one side to six other cells, and the three angling bases of each cell form one-third the base to three other cells. Then how the bees, by their antennae, told in the dark just how to shape their cells, each bee having a rule and a square of its own; how the hexagon form gave the greatest strength with the least waste of space and material, illustrating it with square and round circles, and how the wax was secreted

by the bees consuming honey, the same as the fat of any animal was produced by consuming large quantities of food. How the wax exuded in scales from under the segments on the under side of the abdomen, and how it was taken from there with the feet of the bee and carried to the mouth, illustrating how it was manipulated into comb.

He then told how Huber, the blind bee-keeper of the past, ascertained that it took 20 pounds of honey to produce one pound of wax, and yet with this knowledge, thousands of pounds of wax in comb form was allowed to go to waste in the land, or to be worse than wasted, by breeding hundreds and thousands of the wax-moth to go about to injure the bees of the one who was careful that no bit of comb was allowed to lie about to breed these pests. And yet these wasters thought they knew as much about bee-keeping as anybody, and could not be coaxed to take a bee-paper that their understanding might be enlightened. He said it reminded him of a certain poor church that wanted new hymn-books.

A certain church needed hymn-books badly, but felt too poor to buy them. At last they instructed their clerk to write to certain houses to ascertain the price at which 50 hymn-books could be purchased, and adjourned the meeting two weeks to hear the replies.

When the time came, the clerk read the prices of the different houses, all but one of which wanted \$25 for the 50 books, or 50 cents each. But the exception read, that, if the church did not object to a few advertisements being in the hymn-books, the house would furnish them at 5 cents each, or \$2.50 for the lot. After due consultation, it was concluded that a few advertisements, as is often seen on the covers of our Sunday-school lesson helps, would do no special harm, so the clerk was authorized to procure the books.

It so happened that Christmas of that year came on Sunday, and the books arrived late Saturday night. The sexton hurriedly distributed them among the pews without taking time to look at them, and the preacher, having his own, or one of the 50-cent books, read the first lines of the hymn beginning.

"Hark, the herald angels sing,
Glory to the new born king"

explaining that the same would be very appropriate to Christmas morning, when he sat down.

The organist played the prelude, but imagine the surprise and chagrin of that congregation when they found themselves singing—

"Hark, the herald angels sing,
Beecham's pills are just the thing,
Always sure and very mild,
Two for man and one for child."

Here the audience went into uproarious laughter and applause. As soon as a little calm could be restored, Mr. Doolittle said, "And just so with the man who allows wax to go to waste, but is too poor or stingy to take a bee-paper; he really thinks he is singing the praises of God and practical bee-keeping, when he is only singing for Beecham's pills, to the disadvantage of Godliness, himself and his neighbors."

It soon appeared to me that Doolittle had now reached the part of his theme which he had especially come for. I had wondered that he, only just up from a sick bed, had driven 13 miles over rough roads, and in the cold, to talk to only about 11 persons who were at this time keeping bees, and about 14 others who had at some time in their lives kept bees. How these numbers were ascertained, Mr. D. had taken an expression of the audience soon after he commenced to talk, by asking all who had bees at present to rise, and, when they were seated, ask all who had ever kept bees, but had none now, to rise, which showed the above result, or only about 25 persons out of an audience of nearly 300 or more who had ever been interested in bees to keep a single colony.

As soon as Mr. Doolittle had made the application of his hymn-book story, he continued by asking the farmers if they had ever thought that the bees were the very best friends they and the fruit-growers had? And without waiting for any reply he told them that such was the case, for very much that was raised on a farm could not be raised at all to perfection were it not for the agency performed by the bees and other insects, through their carrying the pollen on their bodies from one flower to another while in search of honey, from such flowers as are not capable of self-fertilization. None of the flowers which secrete nectar will ever bear fruit to any degree of perfection without the aid of the bees. And yet we find farmers all over the country who are jealous of the bees and their keeper, through their ignorance of the prime reason for which they were

created and placed upon the earth. Every farmer raising fruit, the clovers, buckwheat, or any member of the vine family, could well afford to pay the keeper of bees a reasonable sum for keeping them, rather than have the bees removed from their locality. Yet they usually growl about and malign their best friends, being jealous of the small compensation the bee-keeper secures from his bees, thinking the same in some mysterious way might have gotten into their pockets, had not the bees carried it off and put it into the pockets of their keeper.

God created the bee for the especial purpose of pollinization of flowers, and so placed nectar in the flowers, which need pollenizing, to attract the bee. And by and through nectar stored in the flowers and gathered by the bees, their wants are supplied, and they caused to live, so that in return they can fertilize more flowers; and so the flowers and the bees are mutual admirers, the one helping the other continuously, thus causing both to thrive and be happy. This was the sole purpose for which bees were created, but as they were like some farmers he knew of, a little greedy, they would store much more of the nectar than they needed to sustain life, when there was a plentiful secretion by the flowers, and through this trait of the bee there was often a surplus stored, or more than the bees needed that they might live. Taking advantage of this trait, man had come to understand how he could have a sweet "suitable for the gods," and thus we had not only honey for the bee-keeper, but ship and train-loads for commerce.

"Can I prove this point?" said Mr. Doolittle. He then went on to show how among the grasses none secreted nectar in this county but the clovers, and proved by the shape of the flowers, how it was impossible for the clovers to be self-pollenizing through the agency of the breeze, as were the others, hence honey or nectar was secreted by each little flower to attract the bees, that through their agency seed might be perfected. And to clinch the matter he gave history to show how the Australian government had spent thousands of dollars importing bumble-bees from the United States so that they could raise seed from the red clover, which previous to this importation did not give sufficient seed to pay for the harvesting of the crop.

He then took trees of various kinds, and proved the same of them which he had of the grasses, and, as a clincher, told how in a certain township in Massachusetts through jealousy bees were once banished. The next year no fruit came to perfection in the interior of that township, while around the edges fruit perfected as usual, so that through this the jealous people were led to see wherein they had made a mistake, and begged the bees back again, when they had fruit as before.

[Concluded next week.]

CONVENTION PROCEEDINGS

Report of the Northeastern Ohio, Western New York and Northwestern Pennsylvania Convention.

BY ED JOLLEY, SECRETARY.

The Northeastern Ohio, Western New York, and Northwestern Pennsylvania Bee-Keepers' Association held their annual convention at Franklin, Pa., Jan. 11 and 12, 1899. Owing to the prevailing epidemic, "la grippe," and the extremely cold weather, together with the past discouraging season, the attendance was rather slim.

Pres. Geo. Spitzer delivered the annual address, in which he expressed his pleasure at meeting those present. Altho he had hoped to see a larger number of bee-keepers present, he thought that these small conventions were usually as enthusiastic and fully as profitable as the larger ones; and that it was those who failed to attend that sustained the loss.

SPRING MANAGEMENT OF BEES

was the first subject on the program for consideration. Mr. Sutton managed by stimulating weak colonies by feeding, and keeping them well packed until all danger of cool nights was past. He never practiced contracting the brood-nest. Mr. Tubbs contracted the number of combs the bees

could cover, making sure that they had plenty of honey and a good queen, adding empty combs or honey when needed. Mr. Reynolds would feed to stimulate brood-rearing as early as safe. He would feed honey if he had it; if not, he would feed sugar syrup. If the spring was late and cold he would feed artificial pollen and give water.

Some questioned if bees ever needed pollen before natural pollen could be gathered, saying that they believed late fall honey contained pollen sufficient for the needs of the bees in the early spring. The fact that bees will take artificial pollen readily, even greedily, early in the spring, was cited as evidence that bees are often then in need of pollen. Mr. Bair and one or two others had seen their bees gather pollen, or dust resembling it, early in the spring from sawdust-piles.

The question was asked if it paid to feed to stimulate brood-rearing, where there was an abundance of honey in the hive. The majority thought not.

The next question before the convention was that of large or small hives. It was settled as usual, viz.: Some preferred 8, some 9, and some 10 frames. As the old woman said when she kist the cow, "Everybody to their fancy."

Mr. Reynolds' paper, on "The Summer Management of Bees," completed the afternoon session, as follows:

Summer Management of Bees.

Summer management of bees? Why, this is easy enough. If you will give them a wide berth and keep at a safe distance, they will manage themselves. If I am not mistaken, the bee-keeper who sent me the notice, askt me to write on the summer management of bees for dollars and cents. This is what most of us keep—or try to keep—bees for, not merely for our health and the pleasure of coming in contact with the pointed way in which they do business.

We will suppose the bee-keeper has the apiary in No. 1 shape, all colonies ready to be workt as he thinks best—for queen-rearing, section honey, extracting, or the increase of colonies for sale or to keep for his own use. He may fancy rearing queens and bees for sale if the location and surroundings are good. I say this is his line, others would like the producing of comb and extracted honey; this should be their way, but keep this one idea in view.

Produce a No. 1 article if possible, and always sell it for just what it is. We cannot establish a reputation, or a market for the product of our apiary, unless we show our customers that we are to be depended upon, that they will get just what we represent to them. I have found when you gain their confidence it is easy to keep if not betrayed.

Summer management of bees for profit I think must be determined by the bee-keeper himself, for what suits one locality will not answer in another. The same will hold good regarding the season and the bee-keeper himself. Some say that they get just as many pounds of honey as their neighbor, and don't fuss half as much as he does. But a glance at the apiary and honey when ready for market tells for itself who gets the best price from their sales. Let every bee-keeper, after studying the location, the demands of the market, his fancy for the different branches of bee-keeping, choose one or all, and do the best he can. As for the best way to manage bees for profit in summer, I don't know.

But I will give my way when trying for comb honey. Our section of the country is not to be depended upon every year for a good flow, either from clover or buckwheat. I try to have the bees of the right age to gather surplus, if any, and to get them I must figure back from the time I expect the honey-flow. I must count 37 days from egg to the field-worker, and as I cannot get the eggs all laid in one day, I commence feeding to stimulate the bees to feed the queen so she will begin laying six or seven weeks before the honey-flow is expected, if I am to get my bees in shape for the first honey-flow of the season by the queen of each colony laying the eggs.

Sometimes I feed sugar syrup, if I have no unsealed sections left over or brood-combs filled. If the bees have plenty of honey in the brood-combs I will change them, putting combs of honey with the cappings shaved off if necessary between combs of brood. I like this way best, for I have had the least trouble about robbing.

Keep on feeding and changing combs until the honey harvest is at hand. If the bees show signs of swarming, I change a frame of brood with some weak colony for a frame of comb, or put in a frame of foundation.

After the sections are on, if colony we will say No. 1 swarms, put the swarm in a new hive filled with frames of comb or foundation, placing the new swarm on the stand of the parent colony, setting that in some new place. The

next morning take the sections off the old hive and place them on the new swarm. This secures most of the field-bees with the old queen, allowing the bees in the old hive to rear a queen for themselves, and to replace any old queen I may have that does not lay eggs enough to build up her colony good and strong.

If I don't want increase of colonies, I put the swarm that comes from hive No. 2 into hive No. 1, that swarmed first, returning the queen of No. 2 where she came from, and so on through the season, and I have only increased one colony of bees. I use mostly what is called T tin supers, or supers holding 24 sections $4\frac{1}{4} \times 4\frac{1}{4} \times 15\frac{1}{2}$ or 16 or 17, with no separators; the 8-frame hive, the frame about 17 inches long, and 10 $\frac{1}{2}$ deep. I use foundation in the sections from $\frac{3}{4}$ inches wide to whole sheets, always putting the sections containing the narrowest starters in the middle of the super. If the honey-flow seems to be good when the sections are about ready to seal, I raise up the super and put another under it, and continue this as long as the honey-flow lasts.

In the forepart of the season, when it is cool at night, I pack around the supers in the hives with old rags, or quilts made on purpose, paper or burlap sacks, anything to keep them warm, and I have found it pays well for the trouble.

Let us see if we cannot improve in the management of our bees this year, so when the toils of the season of 1899 have been reviewed, and we meet again in 1900 to compare notes, it will not be sorrow and disappointment we report regarding the bees, but words of good cheer and encouragement to all. Let us do our best and leave the rest.

R. D. REYNOLDS.

EVENING SESSION.

This session opened with the discussion of

SUMMER MANAGEMENT OF BEES.

Mr. Sutton managed about the same as Mr. Reynolds. When swarming occurred he managed on the Heddon plan, and depended on the swarm for the surplus. Mr. Peck managed the same for extracted honey as for comb, up to putting on the supers. He used queen-excluders to keep the queen and the pollen below. He would use excluders if he had to pay a dollar apiece for them. By keeping the queen and brood below, he got more honey in the supers, and had more in the brood-chamber in the fall. He workt for both comb and extracted honey, principally extracted. He could produce nearly as much comb as extracted honey, but his market called mostly for extracted. He thought it advisable to run for both comb and extracted honey. Mr. Spittler said if he kept but two colonies he would have an extractor.

FEEDING BEES—OUT-APIARIES OR BEES ON SHARES.

Tapping the question-box brought forth the query, "What is the best method of feeding bees?" The majority used a Mason jar with a cloth tied over it, inverted over the frames. Mr. Sutton took the porcelain lining out of the lid, and punched a row of holes around the outer edge of the lid from the inside. This workt nicely, and was much handier than tying a cloth over the jar. Mr. Bair fed his bees by brushing the honey or syrup into the empty combs with a painter's brush, and hanging the combs in the hive.

The next question was, "Is it preferable to run an out-apiary, or put the bees out on shares?" It was decided that where the owner had time to work an out-apiary it was best to do so; but where he had more bees than time it might be best to put them out on shares. It was considered a fair arrangement for putting bees out on shares, for the owner to let them out for half the honey and half the swarms, each party paying half the expenses for supplies, the owner to get all his old colonies back at the end of a stipulated time. If any of the old colonies died during this time, it was the owner's loss, but he should get the hives and combs.

Mr. Sutton next gave a talk on increasing our honey resources. In brief his ideas were, to plant and encourage the planting of small fruits, white, sweet and Alsike clovers; and where shade-trees were needed, to plant linden.

The next question was, "In producing comb honey is it best to use separators or not?" The majority thought that it was best. Messrs. Sutton and Reynolds used no separators.

The next query was as to whether any one present had tried the fence separators. No one present except Mr. Tubbs had used them, and he found no advantage in their use.

Next in order was a paper by Mr. B. W. Peck, of Trumbull Co., Ohio, on

How to Improve the Conditions of the Local Honey Market.

It is with considerable hesitation and a feeling that I am tackling one of the labors of Hercules that I attempt to jot down on paper a few thoughts on this important subject.

Of course, it might reasonably be inferred that an experience in producing honey and building up a home country-market for the same, covering a period of 18 years, might well give rise to some ideas on the subject that would be of value to other bee-keepers, yet I feel that there is a great difference between marketing honey and writing articles on the same, and however much or little I may convince you that I know about the former, I am certain that when I am done you will be unanimously of the opinion that the latter is out of my line of business. However, if I should happen to stumble on some point that would excite discussion, I should feel that I have accomplished the principal object of a paper of this character.

The first and most important point to be considered in building up and keeping a home market is the *quality* of the honey. Under no circumstances do I attempt to sell anything but well-ripened honey. It should also be of the best color possible. Of course, we shall have to dispose of some dark honey, but our customers should have a fair opportunity of sampling it, and it should be sold at a lower price than the whiter goods. I leave as much as possible of the dark honey in the brood-nest, but even then I have two or three thousand pounds of it to dispose of in an ordinary season. I find that my customers prefer it at the lower price, and as they understand exactly what they are getting there is no cause for complaint. In making my fall sales I usually have the amber, white, and dark honey in the same load, which gives customers a fair opportunity of seeing the difference in quality as well as price, and govern themselves accordingly.

In this, as in all matters pertaining to the marketing of honey, absolute honesty is the best policy. One price to all should be the rule. If one for the sake of closing out a load quickly is tempted to cut the price in the hope that his other customers will not know it, he would better resist the temptation, for such information travels very rapidly, and it will not be very long before some one, perhaps several miles distant, will say, "I understand you sold it for such a price to so and so, and I don't want to pay any more than he does."

A reputation for honest and square dealing will also help us to deal with those who are unduly suspicious of adulteration in honey. There are still some ignorant enough to suppose that granulation of honey is positive proof of the presence of sugar or some other foreign substance therein. I label it all "Pure Honey," and on the label are directions as to what to do if it granulates. It is also necessary to supplement this with extensive verbal explanations in many cases, and how much of it is believed depends largely on the amount of confidence placed in the salesman. I have found it profitable in many cases to leave a copy of a honey-leaflet, which explains clearly the subject of granulation, and explodes some of the popular myths in regard to adulteration. But most important of all is to become acquainted with our customers, and to win their confidence that they may be more ready to accept our explanations of these matters.

In regard to the size of the package, I use cases of 12, 20, and 24 pounds each for comb honey, and about uniformly use 25-pound pails for extracted honey.

In working up new territory it is well to have some smaller package, varying from three pounds to 25. With a small package a new customer may be secured who could not be induced to purchase 25 pounds at first; but after the trial trip I usually follow this up with the uniform size—25 pounds. I find it better to break a package occasionally, or weigh out whatever may be wanted, than to carry small packages; for very many take the large packages without objection who would take the smaller ones instead if they had the opportunity; this would make it necessary to cover the same territory too frequently. As I dispose of six or seven thousand pounds in this way in an ordinary season, I find it desirable to sell it in as large packages as possible.

It is not always desirable, however, to sell all that you can to one individual. There are those who can be induced to take two 25-pound pails at the same time. Some people will thereby become so tired of honey that they will not buy any at all the next season, but will tell you that they have some of your last year's sale still on hand. I would rather make a smaller sale and meet a hungry customer the following season. However, the cases in which one is in danger

of selling more than can be satisfactorily consumed are comparatively rare.

In regard to prices, this will depend of course largely on local competition. In general I think we should get not less than 12 cents a pound for white comb honey, and 8 cents a pound for white extracted; and generally I have no difficulty in getting these prices.

There is one kind of competition however which I would like to hear discussed at this meeting. After long years spent in building up a home market, we are commencing to reap the fruits of our labor, and have secured a long list of regular customers who are looking to us to supply them yearly with honey, when along comes some fresh young competitor, whom you yourself, perhaps in a moment of mistaken benevolence, have started in the business, who, for the purpose of securing your customers, offers it to them at a slightly lower price than you have been receiving. Is this legitimate competition? If not, how is it to be met? Some of the editors of our bee-papers would say, "Get them to subscribe for a good bee-paper;" but I've tried that, and I find that it makes an already unscrupulous competitor a more powerful and effective one. I can't help but believe that if we should induce all the small honey-producers about us to subscribe for bee-papers, it would result in still lower prices. As a question of business policy, can we afford to do it?

I have now, I think, sufficiently indicated some of the conditions of a local market, both favorable and unfavorable. If I have not fully answered the question "how to improve them," I hope I have at least suggested something worthy of your consideration, and that the discussion following may serve to supplement and correct the deficiencies of this paper.

B. W. PECK.

Mr. Tubbs thought that it was not best to try to induce our neighbors to go into the bee-business, or subscribe for bee-papers. The majority however thought that there was room for more good bee-keepers always room at the top and that every bee-keeper should be a reader of bee-literature.

It was thought that many of those who injure the market do so inadvertently, or from a lack of understanding the conditions of the market; and that this condition might be alleviated if there was more fraternizing among bee-keepers, more visiting back and forth, getting better acquainted with our neighboring bee-keepers, and, through discussion, arrive at a better general understanding of the conditions of the market, and how to meet them.

SECOND DAY MORNING SESSION.

"Profitable use of comb foundation." Messrs. Tubbs, Sutton and Reynolds used starters in the sections. Objected to full sheets on account of "fish-bone." All present used full sheets in the brood-frames, except Mr. Silzli, who used starters in both sections and brood-frames.

"Preparing bees for winter." The first preparation was to see that they had a good queen in the fall and plenty of good honey. Nearly all present practiced out-door wintering. Nearly all used double-wall or chaff hives. Chaff, straw or forest leaves was the packing generally used. Mr. Silzli used paper with excellent results.

"How to prevent robbing." Leave no honey exposed during a dearth of honey, and keep good queens in your colonies. Mr. Sutton said he believed that robbing never occurred in a colony that had a first-class queen.

"Making the Association more useful." Mr. Spittler thought that our meetings were very good, but if a larger attendance could be secured greater good to a greater number would result. He thought it would be advisable for the Association to offer some premium—a bee-paper he thought would be a very good and appropriate premium to offer as an inducement to attend the conventions.

The following officers were elected for the coming year: President, Geo. Spittler, of Pennsylvania; Vice-President, B. W. Peck, of Ohio; Secretary and Treasurer, Ed. Jolley, of Franklin, Pa.

Andover, Ohio, was chosen as the next place of meeting.

AFTERNOON SESSION.

Mr. Sutton exhibited his new extension swarming-pole. This pole was made to use an ordinary swarming-box, or any other swarming device. By means of a cord within the pole, its length could be instantly extended from 12 to 22 feet, or any intermediate length desired.

It was originally designed to have some bee-keeper of long experience give a sort of reminiscence. In the absence of such a paper it was decided to hold a regular old

Methodist experience-meeting, except that our experiences should be about bees and things kindred. This was really one of the most enjoyable features of the convention—one in which all took part. Had any of the uninitiated been in the corner listening, they might have thought, "What great fishermen those fellows would have made!" It would be superfluous to attempt to give each one's experience here in detail, nevertheless these experiences were thoroughly enjoyed by all present. But I cannot refrain from giving a part of what Mr. Bair said.

Mr. Bair is a veteran—a veteran soldier and a veteran bee-keeper. After giving some of his more common-place experiences, he told us some of the curious superstitious ideas in vogue when he commenced bee-keeping. "In those days," he said, "when a swarm of bees came out, and you had not the necessary things at hand to make sufficient noise, if you ran into the kitchen and took a loaf of bread, turned it upside down on the table, and plunged a knife down through the loaf into the table, the swarm could not possibly go away, but was sure to settle. If you had everything ready, and the family all at home, a loud noise was all that was necessary to cause them to settle. If, perchance, they had started to leave before you discovered them, if you could run ahead of them and turn your hat upside down on the ground the swarm could not possibly pass over it. If you succeeded in getting them hived, if you would go to the pig-sty and get some dirt and put it on top of the 'skap,' it would be impossible for the bees to leave. If a member of your family died it was necessary to go and tell the sad news to the bees, or else you would never have any more luck with them."

A number of other experiences were fully as ludicrous and enjoyable.

The convention adjourned to meet at Andover, Ohio, Jan. 12 and 13, 1900.

ED JOLLEY, Sec.

them a queen. It's a little doubtful if you'll have a chance anyhow, for a queenless colony put in the cellar doesn't generally come out alive, and if it does the bees are likely to be so old that it will only be an aggravation to give them a queen, for they will be rapidly dying off and will make very slow work building up to a colony that's worth anything. The wise thing will be to unite them with a weak colony, or divide them among several. Do this as early as the weather is warm enough for bees to fly freely.

What About Catalpa for Bees?

Do you know anything about the catalpa tree for honey? I have about 60 of them, and they were loaded with blossoms and bees last spring.

MENDOTA.

ANSWER.—I don't know. My impression has been that they are not of much value, and yet the fact that bees are plenty on them is pretty strong evidence that they are of value. Even if the bees get only a little nectar from them, or if they get only pollen, it's just that much more than they'd otherwise get, for the bees wouldn't work on them if they could do better elsewhere.

Closed-End vs. Open-End Frames—Foundation Fasteners for Sections.

I am situated so that my bees have abundant pasturage on willow early in the spring, followed by dandelion, April flowers and other wild flowers. Large fields of wild mustard are in full bloom by June 1, but bees do not gather any surplus honey from it. By the last of June wild clover is in full bloom which yields our main flow of honey.

1. Under these circumstances, do you think that the closed-end frame hive would induce bees to breed up faster in the spring than in the ordinary Hoffman frame, so as to be in full force to work on clover to the best advantage, and probably gather some mustard honey?

2. Which foundation fastener for sections do you recommend?

3. What is your opinion of the A. C. Miller fastener?

OSAKIS.

ANSWERS.—1. With the ends entirely closed, the bees are warmer for winter and warmer for breeding up in spring, but the advantage is more than counterbalanced by the inconvenience in handling, unless I am mistaken, and I don't believe there would be enough difference made to allow a harvest from flowers earlier than open-end frames would allow. But where propolis is scarce there is not the same objection to closed-end frames, and with propolis as plenty as it is with me, Hoffman frames are by no means desirable.

2. I've never tried anything that does better than the Daisy fastener.

3. It doesn't work as well for me as the Daisy.

A Bunch of Ten Questions.

1. What kind of bees are the yellow-banded Adel bees? Are they good honey-gatherers?

2. Will bees finish queen-cell cups when they have a fertile queen?

3. I have some partly-filled sections where honey is partly candied. Is there any use I can make of them, or will the bees clean out the candied honey if I put them in supers on the hives next spring?

4. Are tin supers better than others? and do sections come out of tin supers cleaner than wooden ones?

5. Is it well to divide when bees swarm and return to their hive when they have a clipped queen?

6. Will capt queen-cells hatch out in an incubator?

7. I have some moldy frames of honey which I kept over winter. Will it do any harm to give them to the bees next spring?

8. About how many eggs does a young queen lay?

9. To-day it was warm, and my bees wanted to fly, but the ground was covered with snow, so I put on the entrance of the hive some wire-netting. Was that all right?

10. How close, or how much, do you cut the queen's wings?

NEW JERSEY.

ANSWERS.—1. I never saw any of them. If I am not mistaken, it is a strain of Italian bees to which that name

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[Questions may be mailed to the Bee Journal, or to Dr. Miller direct.]

Moving Bees the Middle of February.

I have my bees in the cellar (Feb. 14), but as I have moved about eight miles from them I would like to move them, as the man that lives in my house doesn't know anything about bees. If I move them now I can use a sleigh. Will it be all right if I move them and give them a slight before putting them into the cellar here? I would like to have them here, but I don't want to do anything that will harm them. I have only 11 colonies; they are hybrids and golden Italians.

WISCONSIN.

ANSWER.—So near spring as this there would be little risk in handling them and putting them directly into the cellar, as they will not likely be confined there very long at farthest. But it may be still better to wait a little later, and set them directly on the summer stands.

What to Do with a Queenless Colony.

One of my colonies, a swarm of last summer, did not do well, while the other colonies stored from one to three supers each full of honey. This one colony filled the lower box all right, but did not do anything in the super, and showed a forlorn appearance during fall. I believe the colony is queenless, but my perception came too late—I had my bees in the cellar before I knew the probable cause of inactivity. I dare not examine the colony while in the cellar, but as soon as I can put them out, I shall examine it and find whether it is queenless. My question is: Would it be advisable to introduce a new queen if queenless? and when would be the proper time to do it?

IOWA.

ANSWER.—If you have only lately commenced keeping bees, the advice to give you is to give the bees a queen as soon as you can get one for them in the spring. Not that such advice is at all good; but it's the only advice you'll follow. If, however, you've kept bees long enough to be a little toughened, then my advice is not to think of giving

is given, just as you might take a colony of Italian bees and give them a particular name.

2. That depends. If you look into almost any hive containing a colony, you will find a number of queen-cell cups that will remain unfinished until the bees think of swarming, when they will be occupied and finished. They will not be occupied and finished unless a fertile queen is present, for if the queen is taken away, instead of rearing a queen in one of these cups, a larva in a worker-cell will be chosen.

3. If the least bit of honey has candied, it is doubtful that you can get them cleaned out so they will be good to use again.

4. I never before heard of "tin" supers, and I doubt whether such are in use. It is probable you have reference to T tin supers, or, as they are generally called, T supers. The only tin about them is the bottom supports on which the sections rest, and these are called T tins because a cross-section looks like the letter T inverted—L.

5. The common practice is to set the old hive to one side, let the swarm return to a new hive placed on the old stand, and let the queen go in the new hive.

6. Yes, a sealed queen-cell will hatch out a queen if kept anywhere warm enough.

7. That's the best thing to do with them, only you mustn't give one colony so many at a time as to discourage it. You may give to a colony as many as two or three at a time outside of its brood-nest.

8. She lays one at a time. When she first begins to lay she will lay very few in a day, but when she gets fairly warmed up to the work—say when the white honey harvest is about at hand—she will not think it a very big thing to lay 2,000 or 3,000 every 24 hours.

9. You might have done better. That left the light shining in and the warmed air coming in, urging the bees in the strongest way to come out for a play-spell, and the fact that they are fastened in seems to make them all the more fierce to get out, so that it is quite possible more bees die in the hive than would die on the snow. The better way would have been to put boards or something of the kind in front of the hive so not a ray of light could enter.

10. A queen has four wings, two on each side. Cut the two on one side as short as you conveniently can.

Number of Colonies to a Load.

How many colonies do you commonly put on a wagon at a time? ILLINOIS.

ANSWER.—Generally I put on all the wagon holds 31 colonies. Nine of these go in the body of the wagon under the rack, the other 22 on the rack.

Bees Flying Early Robbing Clover Best Size of Hives, Etc.

1. Is it early to have young bees in the hive? I had some that took a flight Jan. 15.

2. I have a strong colony that is queenless. Will they rear a queen now if I give them some brood, before natural pollen comes in?

3. I have some bees that want to rob. It seemed that they got a start at a queenless hive, and I put them into the cellar, yet there seemed to be quite a number working around all the hives. What shall I do? Do all bees rob to some extent during warm days in winter?

4. What kind of clover would you recommend for this State (Tennessee), sweet or Alsike? We have red clover, but it doesn't yield nectar as well.

5. What kind or size of hive is best for comb honey, 10-frame or 8-frame? I use the standard Langstroth 10-frame.

6. Will bees store honey enough in an 8-frame hive to winter on? TENNESSEE.

ANSWERS.—1. Generally no brood will be found as early as Jan. 15, altho it is quite common to find breeding commence in February when bees are wintered out-doors. If the bees that flew Jan. 15 had just emerged from their cells, that was remarkably early. It is possible they had emerged so late in the fall that they still appeared young.

2. They might, but it would not be very successful, and the wisest thing you can do is to unite them with a weak colony that has a good queen.

3. You can't get bees so honest that they'll never rob if the temptation is great enough, and you can't do anything with the robbers to stop them. The only thing is to keep

everything as safe from them as you can, not exposing honey and not keeping weak and queenless colonies.

4. Sweet and Alsike ought both to do well with you. Unless your stock has learned to eat sweet clover, you may find Alsike the more profitable for forage. Likely an acre of sweet clover will yield more honey than Alsike, but you must consider its other value as well as its value for honey.

5. It depends much on the management. Unless a good deal of attention is paid to them, 10-frames are better.

6. Sometimes, and sometimes not. If the combs are kept filled with brood until pretty late, there is hardly room enough for honey. If left to themselves there is more danger of suffering for want of stores in 8-frame than 10-frame hives.

Getting Bees to Empty Partially-Filled Sections.

On page 98, near the beginning of the page, I see a way given to get honey emptied out of sections. Now what I want to know is this: If I put on a hive a super of sections partly finished, and then put over that another super having sections with a little honey in them, will the bees carry down the honey out of the upper super? SUBSCRIBER.

ANSWER.—So far as I have tried anything of the kind—and I have tried it extensively—it has been an utter failure.

Using a Bee-Escape How Much Comb Foundation - Transferring from a Tree.

1. Can I use a bee-escape on an improved Langstroth-Simplicity hive without a super? or will I have to use supers? If so, would it be well in this part of the State to use double supers?

2. How much comb foundation do I require through the summer for two hives? and which is the better, the extra thin surplus or the thin surplus, if I use a one or two inch starter in an 8-frame hive for comb honey?

3. How can I transfer a swarm of bees from a tree in the woods? Will I have to cut the tree off so short that I can carry the trunk home, or can I take a hive along to the tree and transfer them there? What is the best way to do this, and what time of the year?

4. Which bee-book do you consider the better for a beginner, the "ABC of Bee-Culture" or Prof. Cook's "Manual of the Apiary." MINNESOTA.

ANSWERS.—1. I'm not entirely sure whether I understand your question. There's hardly any need of a bee-escape unless you have something in the line of a super, understanding, of course, that by a super is meant anything that is put over the hive in which to have surplus honey stored. It may be a super to contain sections, or it may be a super to contain extracting-combs. In either case an escape can be used. If by "double super" you mean two supers on a hive at a time, it is generally advisable to have more than one super on at a time if there is a good honey-yield and the first super is pretty well advanced. If I haven't struck the right idea, ask further and I'll try again.

2. I don't know which is better, altho I have generally used the thin. When not storing, the bees are likely to gnaw the extra-thin more than is desirable. To be sure, supers should not generally be left on the hive when bees are not storing, but one wants them on a little before storing begins, and sometimes there is a temporary lull when the bees stop storing for a very short time and then begin again. One pound of foundation will probably do for what you require.

3. Either way will answer; whichever is most convenient for you, taking all things into consideration.

4. Probably no bee-book in the world is fuller of practical information than the "ABC of Bee-Culture." "Cook's Manual" contains information that is lacking in the "ABC of Bee-Culture" as to the natural history of the bee from the stand-point of an entomologist, as well as giving practical information. I wouldn't like to spare either of them, nor would I like to be without Dadant's Langstroth.

Langstroth on the Honey-Bee, revised by the Dadants, is a standard, reliable and thoroughly complete work on bee-culture. It contains 520 pages, and is bound elegantly. Every reader of the American Bee Journal should have a copy of this book, as it answers hundreds of questions that arise about bees. We mail it for \$1.25, or club it with the Bee Journal for a year—both for only \$2.00.

GEORGE W. YORK, Editor.

[Entered at the Post-Office at Chicago as Second-Class Mail Matter.]

United States Bee-Keepers' Association.

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., E. Whitcomb; Vice-Pres., C. A. Hatch; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GEN'L MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

VOL. 39.

MARCH 9, 1899.

NO. 10.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

The Dot Contest Prizes we expect to close up in the next issue of the Bee Journal. Judging from the number of responses we have received to our suggestion that the cash winners donate their prizes to the Langstroth Monument Fund, we think that about half of them have done so. This should make an addition to that Fund of about \$50. But next week we will know exactly, and we will also remit to the balance of the winners the several amounts due them. We would have done this before now, but we have all been so busy in the office that we could not well reach it. And then, we wanted to give *all* the winners a good chance to contribute to the Monument Fund.

Philadelphia, Sept. 5, 6 and 7.—The following notice is sent us by Dr. A. B. Mason, the Secretary of the United States Bee-Keepers' Association, which we are glad to give a place in these columns:

TOLEDO, OHIO, Feb. 27, 1899.

The Executive Committee of the United States Bee-Keepers' Association has complied with the request of the members as expressed at the Omaha convention, and decided to hold the next convention of the Association at Philadelphia, Pa., commencing Tuesday evening, Sept. 5, holding three sessions on Wednesday, and three on Thursday, the last being on Thursday evening.

The program is being prepared, and arrangements are being made for the entertainment of those in attendance on the meetings. Notice of exact place of meeting, railroad and other arrangements, will be given in due time.

The Philadelphia Bee-Keepers' Association, with only one exception I believe, is composed of amateurs, who are keeping bees for pleasure, and not profit in dollars and cents, and its members are showing quite an amount of in-

terest in the coming convention; and in a recent letter from its Secretary, in speaking of securing rates, and places for delegates, he says: "I can assure you that we will do everything we undertake to do in a thorough manner." So we shall have a cordial reception, and an interest taken in our comfort.

A. B. MASON, Sec.

We hope that just as many of our readers as possible will begin to make their arrangements to be present at the National Convention in September—during the Grand Army meeting, when railroad rates will be low.

Some Wisconsin Statistics for 1898.—We are informed that the apiarian output among manufacturers in Wisconsin during 1898 was as follows: 30,000,000 sections; 100,000 hives; and 30,000 pounds of beeswax made into comb foundation. These figures do not include the supplies handled by dealers, simply manufacturers. Of course Wisconsin stands at the head in the output of sections and hives; and likely Ohio would come next.

Bee-Keeping as a Sole Business.—The Question-Box of this journal lately discuss whether it is safe to depend upon bee-keeping alone for a livelihood. Editor Hutchinson quotes approvingly the answer of C. P. Dadant, "Yes, provided you do not keep less than 300 to 500 colonies," and says if a man keeps only enough bees to make a living in a good season, a bad season will oblige him to add some other business. He thinks the best thing to add is *some more bee-keeping*.

The Michigan Foul Brood Bill.—Hon. Geo. E. Hilton, President of the Michigan Bee-Keepers' Association, has sent us a copy of the proposed Foul Brood Bill now before the State legislature, with the request that we give it space in the Bee Journal. It reads as follows:

SEC. 1. The people of the State of Michigan enact that upon the recommendation of a majority vote of the members of the Michigan State Bee-Keepers' Association, the governor shall appoint for a term of two years a State inspector of apiaries, who shall, if required, produce a certificate from the governor that he has been so appointed.

DUTIES.

SEC. 2. The inspector shall, when notified, examine all reported apiaries, and all others in the same locality not reported, and ascertain whether or not the disease known as foul brood exists in such apiaries; and if satisfied of the existence of foul brood, he shall give the owners or caretakers of the diseased apiaries full instructions how to treat said cases, as in the inspector's judgment seems best.

DESTRUCTION OF BEES.

SEC. 3. The inspector, who shall be the sole judge, shall visit all diseased apiaries a second time, and, if need be, burn all colonies of bees and combs that he may find not cured of foul brood.

VIOLATIONS.

SEC. 4. If the owner of a diseased apiary, honey or appliances shall sell, barter or give away, any bees, honey or appliances, or expose other bees to the danger of the disease, or refuse to allow said inspector to inspect such apiary, honey or appliances, said owner shall, on conviction before a justice of the peace, be liable to a fine of not less than fifty dollars, or more than one hundred, or not less than one month's imprisonment in the county jail, nor more than two months' imprisonment.

ANNUAL REPORT.

SEC. 5. The inspector of apiaries shall make an annual report to the governor of Michigan, giving the number of apiaries visited, the number of diseased apiaries found, and number of colonies treated; also the number of colonies destroyed by fire, and his expenses.

EXPENSES.

SEC. 6. There is hereby appropriated out of any moneys in the State treasury, not otherwise appropriated, a sum not exceeding five hundred dollars per year, for the suppression of foul brood among bees in Michigan. Said in-

spector shall receive four dollars per day and traveling expenses for the actual time served, which sum shall not exceed the moneys hereby appropriated, to be paid by the State Treasurer upon warrants drawn and approved by the Governor.

SEC. 7.—This Act shall take effect and be in force from and after its passage and publication.

SEC. 8.—By this Act all previous legislation on the subject of foul brood on the statutes of Michigan is hereby repealed.

Mr. Hilton also desired us to again urge all bee-keepers in Michigan to write at once to their senators and representatives at Lansing, urging them to favor the passage of the Foul Brood Bill as above.

DR. C. C. MILLER was in Chicago last week attending the third quarterly meeting of the Chicago Bee-Keepers' Association. It is just wonderful how young he keeps. He is 67, and Dr. Peiro, when so told, said, "Why, he doesn't look a bit over 50." But may be it's a habit doctors have—of looking young. Now, Dr. Peiro is 59, and he doesn't look much over—well, 45. Of course doctors *ought* to know how to keep looking young while they help to make the rest of us look old!

REDBUG NOT BEDBUG.—Mr. O. O. Poppleton, of Dade Co., Fla., wrote us Feb. 28:

FRIEND YORK: On page 115 of your issue for Feb. 23, first column and last paragraph, the word "bedbug" is printed for "redbug." Please correct the mistake, as the balance of the paragraph reads rather funny as it is.

Bees are doing the poorest in building up this winter I have ever known them to do here. The reason is because the extensive fires last spring destroyed our winter pasturage.

O. O. POPPLETON.

DR. C. A. DAVID is one of Chicago's eminent medical specialists. He was born in 1845, in Richland Co., Ill., and came to Chicago in 1875, when he decided to devote himself exclusively to one class of diseases—that of the rectum—such as the treatment of piles, fistula, irritable ulcers, strictures and the like. He then took a thorough course at the University of New York, graduating therefrom in 1882. Dr. David has superseded the old methods of torture with a more rational treatment, and, as a consequence, success has attended his efforts, and by the profession at large he is recognized as an authority. His success may best be summarized by the simple statement that of the vast number of treatments which he has given, aggregating nearly 100,000, he has never lost a case.

We have recently had occasion to patronize Dr. David, and are glad to recommend him to all who require the kind of service he can so successfully and satisfactorily perform. His office is in the Champlain Building, northwest corner of Madison and State streets, Chicago. To our mind he exemplifies to the fullest degree the highest ideal of the Christian physician.

MR. FRANK McNAY, of Wisconsin, who with his wife, has been spending the winter in California, wrote us as follows from San Francisco, Feb. 29:

FRIEND YORK: California seems to be doomed to another year of severe drouth, as there has been no rain for several weeks, and only about an aggregate of three inches in most locations in Southern California, and but little more up here. Bee-keepers are fast losing hopes of a sufficient amount of rain to secure any honey, and bees are being shipt to Arizona and Utah.

The very small amount of rain and exceptionally fine warm weather have afforded us an excellent winter for touring. Mr. J. H. Martin (Rambler) was our near neighbor while in Los Angeles, and on our Rambler wheels we enjoyed many long rambles to the country and mountains with "Rambler" as our guide.

Before leaving Los Angeles we enjoyed an ocean voyage to San Diego and return. I also had a very pleasant visit with Mr. Harbison, and a drive of 25 miles out to his large apiary, which is an ideal location on his 700-acre ranch in a mountain canyon.

I also took a ride by wheel over the Mexican border, returning by way of Coronado Beach and the famous hotel.

We have now spent a week looking over San Francisco, Oakland, the Golden Gate Park, Sutto Heights, and the Beach, and I took a wheel-ride to San Jose, 45 miles down the Bay, through a fine farming and fruit valley. But we do not enjoy this part of the State as well as Los Angeles and vicinity, and we will soon leave the coast, as we wish to spend a few weeks in Salt Lake City and Denver before returning home.

FRANK McNAY.

We are glad our friends have enjoyed themselves so much in California. Some day we hope to be able to follow their example, and ramble around awhile in winter in a warmer clime.

DR. PEIRO, when on his trip West last fall, also visited the States of Oregon and Washington. He has this to say about them:

I have given much thought regarding the matter of migration to either of the above States since a personal observation of the several encouragements each offer, particularly in an agricultural and horticultural sense, and conclude that to the young man of brains and brawn anxious to "get on in the world" a well-selected piece of land for a farm home in either of these States is preferable to the drier altitudes of Arizona, California, or even Idaho. Much moisture can be depended upon to insure regular crops, and the market for any produce is fully as favorable.

Because of the plentiful and natural irrigation, fruits are abundant, small grain yields fine average crops, and hay (alfalfa, especially) is always and bountifully to be depended on. Hence to the young, or even middle-aged, blest with health and a willingness to work, I suggest they investigate the possibilities of these comparatively new but fast-growing States. From a climatic point of view I should deter the weak, consumptive or inflammatory rheumatic patient from going there.

DR. PEIRO.

THE UNION COMBINATION SELF-FEED RIP AND CROSS-CUT SAW, while it is designed for wood-workers generally, is especially valuable for making bee-hives, frames, etc. This machine and attachments are suitable for ripping, cross-cutting, mitring, rabbeting, grooving, graining, dadoing, boring, scroll sawing, edge moulding, beading, etc., thoroughly practical in every particular, and easy to operate. It has a large combination wood and iron table, 28x36 inches, with extension rolls, four changes of speed and three changes of feed. It has babbitt metal lined boxes which are adjustable to take up the wear; has steel shafts and machine cut gears; has foot power with a walking motion, and a chain belt attachment for fast speed. A complete illustrated catalog fully describing this machine and attachments, also a full line of wood-working machinery, will be sent on application. Send for catalog "A." Address the manufacturers, The Seneca Falls Mfg. Co., 46 Water St., Seneca Falls, N. Y., and say you saw their advertisement in the American Bee Journal.

EDITOR HUTCHINSON, of the Bee-Keepers' Review, had this to say in his February number:

"The American Bee Journal began the year with a new dress of type and a number of little nicknacks that add to the beauty of its personal appearance. By the way, this journal recently printed 15,000 copies; the extra copies to be used as samples. This is probably the largest single issue of any bee-journal that has ever been printed in this country."

Many thanks, Mr. Hutchinson. But the number we printed in that large edition was 16,000. You mist it by only 1,000.

I. J. STRINGHAM, 105 Park Place, New York, N. Y., has sent us his catalog of bee-keepers' supplies for 1899. He is one of our regular advertisers, and will be glad to mail his catalog to all who will write him for it. Please mention the American Bee Journal should you write Mr. Stringham or any others of our advertisers.

Long Heating Darkens Wax, as also does frequent re-heating, altho slow cooling allows the impurities to settle to the bottom, says Editor Root.

Smoking Bees When Taking from the Cellar is recommended by C. Davenport, in the Bee-Keepers' Review. It helps to keep the bees from mixing up and going into the wrong hives, and no harm comes from the smoking. An acquaintance of his prefers a windy day for taking out, as bees fly closer to their hives, thus mixing less.

Moths will not Trouble Dry Combs, if such combs are entirely free of honey, pollen, or cocoons. J. B. Hall told the editor of the Bee-Keepers' Review that an excluder keeps the queen out of extracting-combs, the bees lick them clean at the close of the season, then there is no trouble from worms, even if the combs are stacked up in hives outdoors and the hives left open to the moths.

Do Bees Freeze?—Dr. Miller discusses the question in the Progressive Bee-Keeper, and says that while it is true that bees enough in a cluster, with air and food enough and cleansing flights enough, are in no danger of freezing, yet with some of these conditions lacking they may freeze in a temperature not so very low; and that when the unqualified statement is made, "Bees never freeze; they starve," the answer should be, "Bees do freeze, millions of them."

Does Black Anger Bees?—J. H. Martin thinks color does not make so much difference as texture and cleanness. Fuzziness is more than color, a fuzzy hat, white or black, attracting attention, and a hole in such a hat being a special target.—Bee-Keepers' Review. Those who say they have seen bees make a distinction on account of color may be hard to satisfy that there is no such thing by the testimony of those who have never observed it.

American Hives Larger than German.—In Germany, bee-keepers in general don't know what a large hive is. Only lately I was reading how a German bee-journal made fun of the French for using the large Dadant hives, and when a large yield is reported from such hives they call it pure humbug.... I may further say that here in America entrances are very much larger than in Germany, and the bees seem to prosper with them.—L. v. Stachelhausen, in Deutsche ill. Bztg.

A Point in Favor of Small Hives, and a strong point in his estimation, is given by the editor of the Bee-Keepers' Review. If the bees get started with more honey in the brood-nest than brood, or even half as much honey as brood, the *habilit* of storing in the brood-apartment has become so strong that they will not give it up. He especially values the practice of giving at the opening of the harvest a super of drawn combs, thereby inducing the bees to *begin* their storing in the super.

Nailed Sections Preferred. Says G. M. Doolittle in the Progressive Bee-Keeper:

"I consider that nailed sections are enough better for shipping honey, to more than pay for the extra time spent in nailing them, for the loss by breakage with other than nailed sections runs so much greater than with the nailed that the damage through breakage will more than hire the sections nailed, or pay the bee-keeper for his time when nailing them himself."

A New Separator is described by Jacob Alpaugh, in the Bee-Keepers' Review. The separators are supported in the super by a strip of tin at each end of the super, the same as in a T super, but instead of a T tin the sections are supported by strips of tin fastened to the separators. These pieces of tin are 1½ inches long and ½ inch wide, ¼ inch at the bottom being turned at right angles to support the corner of the section. Some one got up something of that kind before. Was it L. A. Aspinwall?

Bees Needed for Fruit.—Press Bulletin No. 8, of the Kansas Experiment Station, says:

"If bees are kept from fruit-blossoms by netting or other artificial means, the amount of fruit set is little or none. It not infrequently happens that inclement weather prevents or hinders the flying of bees during the period when the flowers are receptive. A fruit-tree, half of which was subjected to a continuous spray of water during the flowering period, produced no fruit upon the sprayed portion, but an abundance upon the other. A failure due to the above-mentioned cause cannot well be prevented, but may be modified by having bees near at hand to utilize the short favorable periods which do occur.

"An insufficient supply of bees will hinder the setting of fruit. While other insects may take part in the carrying of pollen, the fruit-raiser must rely chiefly upon honey-bees. Experience shows that the hungry bees may fly two or three miles, hives should be within half a mile of the orchard or small-fruit patch."

Boiling Foul-Broody Honey is discust by the Bee-Keepers' Review without reaching any positive conclusion as to how long boiling is required. If the work of the scientists is to be counted, Editor Hutchinson thinks Dr. Miller may be justified in demanding 2½ hours. But he seems to think we can't count too much upon what the scientists find out, and cites, among other things, that Cheshire reported foul brood spores in the eggs of a queen, while a queen from an infected colony has never carried the disease to another colony. That leaves the possible inference that Cheshire was mistaken as to finding spores in eggs. After Mr. Hutchinson had written this, he made a visit to Guelph, Ontario, had an interview with Prof. Harrison, the bacteriologist, and saw some things through a microscope. Instead of knocking into pi what he had written, with admirable frankness he lets it stand, and adds that through that microscope *he saw with his own eyes spores in an egg*. Perhaps it is well for all to avoid being too positive, no matter which side we are on.

Baits in Supers Help to Prevent Swarming.—A Stray Straw in Gleanings says: "If L. Stachelhausen is correct, as I think he is, as to the effect of baits in supers, page 85, then they form quite a factor in prevention of swarming. Forcing bees to begin on raw foundation in the super by the crowded condition of the brood-nest is forcing them just so much toward swarming. [This is a good point. It is one of the golden nuggets that appear in the ordinary articles of some of our contributors, but which the editor had not seen. I now desire to give it all the prominence I can, as I believe there is a good deal in it. Ed.]

Winter Protection.—D. W. Heise—the man that notes and picks for the Canadian Bee Journal—is getting ready for himself a whole lot of trouble. He has so little respect for generally accepted opinions that he says if the cluster of bees is properly protected on top and sides, he would rather have his hives out in the open plain than surrounded by evergreen hedges or high board fences. When too much protection is given by buildings, fences, etc., the bees venture out when too cool for their safety, while the bees in the open mind their business and stay at home.

Liquefying Extracted Honey Before Selling is a mistake in the opinion of D. W. Heise. Instead of taking that trouble, he sells his honey in whatever condition it happens to be, taking pains to instruct his customers what they must do to liquefy it, and finds his advantage in doing so.—Canadian Bee Journal.

Heise's head is level. No matter what pains you take in liquefying, the honey will granulate in your customers' hands, and if they do not know how to liquefy it, your trade will suffer. You may as well instruct them properly in the first place.

When Should Bees be Taken from Cellar? C. Davenport thinks if bees winter well and are nearly dormant they should be left till settled weather; but if restless and uneasy, many leaving their hives and dying, the sooner they are set out the better. If in an intermediate condition, it matters not whether they are taken out in March or April. More stores are consumed if the bees come out early, but they will be stronger for the harvest if early weather is good. If the weather is bad, then those left in the cellar are better off.—Bee-Keepers' Review.

Root's Column

This is a **Queer World**. We cannot be made to see all things alike. Some like one thing, and some another. There is a class, no doubt, who hesitate to try Plain Sections because of the extra expense of the fixtures. There is another class who would not have them anyhow. Well, we are prepared to suit everybody. We have just brought out a slat separator to take the place of the ordinary tin or solid-wood separator.

They are simply four slats bound together at the ends by folded tins. They can be used in any super taking the old-style sections; and their cost is hardly any more than wood separators. We can supply them for 80 cents per 100, either for T supers or for section-holders. For odd-sized supers, of course we shall have to make additional charge. They can be supplied with our regular S super—that is, the supers with old-style sections and section-holders, or with our regular T supers.

Mr. J. E. Crane produced several thousand pounds of honey with separators of this kind, and he is of the opinion that the freer communication afforded gave him fuller and better boxes; but the boxes were hardly as complete and nice as those from fences.

Keep Your Eye on this Column, as we may be able to save you dollars.

The A. I. Root Company
MEDINA, OHIO.

GENERAL ITEMS

Prospects Good for Honey.

According to present indications Southern Indiana, and especially Vanderburgh county, will have a good honey-yield for the season of 1899. We have had the largest rainfall for quite a number of years. A heavy snow falling just immediately before the recent cold wave, when the mercury reached 15 degrees below, saved the most of our young honey-plants from freezing out. I examined and found the roots of the dry weather honey-vine to have withstood the cold weather nicely, thus insuring a bountiful supply of rarest nectar from this source, should the summer be hot enough. However, clover does not look so well, altho it is somewhat early in the season. Large losses of bees are reported all around.

J. C. WALLENMEYER.
Vanderburgh Co., Ind., Feb. 23.

Bees Had Good Flight.

Bees had a good flight Feb. 21. My 34 colonies all seem to be in fair condition. I have thus far lost none.

JOHN STROEBEL, JR.
Saginaw Co., Mich., Feb. 27.

Don't Depend on Neighbors.

I have four colonies of bees. I bought one colony in 1896, and that year they did not get a pound of honey; they would have starved if we had not fed them. The year 1897 we got about 100 pounds, mostly from sweet clover, but some heart's ease. The year 1898 we got 275 pounds. My husband was discouraged; he could not work with the bees, as his work kept him so busy that he had no time to spare. We sent for our neighbor every time there was anything to be done with the bees, so last year I told my husband to send for a veil and smoker, and I would help take care of them myself. This thing of depending on someone else is all nonsense.

We just pack our bees and left them on the summer stands. It is very cold at present—five degrees below zero.

RENA LAFORGE.
Cowley Co., Kans., Feb. 6

Bees Working Hard.

I have 115 colonies of bees in good shape, and the prospect are for a good year. We are having fine weather. Pussy willows are in bloom and bees are working hard.

Kings Co., Cal., Jan. 8. B. P. SHIRK.

Doolittle's Funnel for Making Nuclei

What is the size of the bee-funnel recommended by Mr. Doolittle to shake bees into, when making nuclei? What I want are top and bottom dimensions.

J. N. LADENBURGER.

[We referred the above question to Mr. Doolittle, who answers as follows:—Ed.]

ANSWER.—I think that the funnels used by the A. I. Root Co., and others, in putting up bees by the pound, were an oblong at the top, the sides being perpendicular till coming near the bottom, when a gradual slant was made till the outlet to the funnel was reached, which outlet should be not less than 2½ inches in diameter, in any funnel made for this purpose. If smaller than this, the bees will clog in this narrow part, when a full frame of them are shaken in at once, a thing which we nearly always want to do.

But I had my funnel made the same as an ordinary funnel is made, the top of which was 16 inches in diameter, the sides gradually sloping, at about the angle used in the

SEED DUE BILL FREE

Get new customers to test my seeds. I will mail my handsome catalogue for 1899, lithographed and beautifully illustrated, and a 10c. Due Bill, good for 10c. worth of seeds for trial, absolutely free. It is full of bargains. All the Best Seeds, Bulbs, Plants, Roses, new Fruits, Farm Seeds, Potatoes, etc., at lowest prices. Ten Great Novelties offered without names. I will pay \$50. ordinary small funnel, till they reach the outlet, which was 2 1/2 inches long by 2 1/2 inches in diameter. After it was made I bent the sides in at two opposite points till the top was of an oval shape about 19 inches across the long way by one foot the short way. And this is the only funnel I have ever had or ever seen, and it works completely with either the Gallup or the Langstroth frame, the Langstroth frame being held endwise in the funnel when shaking the bees off the comb. I use this funnel much, in connection with the nucleus-box, and should consider no apiary complete without the funnel and the box, for with them we can make "swarms" or nuclei at our pleasure. G. M. DOOLITTLE.

Wintered Well So Far.

I have been a regular subscriber to the American Bee Journal now for 17 years, besides several copies in the earlier days. My bees have wintered well so far.

EMIL J. BAXTER.
Hancock Co., Ill., Feb. 4.

Fears Loss by the Cold.

Thermometers in this section are indicating from 25 to 30 degrees below zero to day. I fear my entire apiary will be swept away by the extreme cold, as they were poorly fixt for winter. An early snow and freeze caught me napping. My bees haven't had a good flight for some time. J. M. YOUNG.
Cass Co., Neb., Feb. 11.

A Rather Poor Year for Bees.

We have had a rather poor year for bees in this section of country. I have 45 colonies of bees and only had about 500 pounds of comb honey. My apiary is located on Green River, in McLean Co., Ky., on a bluff about 200 feet above low water mark.

J. W. COLTHART.

A Queen Experience.

About Nov. 1 I found a colony that had a drone-laying queen—a young queen. She had a deformed wing; in fact, one wing was all twisted up in something like a web, and fully half of the colony were drones, and the comb was full of drone-brood. I killed the queen, and I had a good queen to give them, which I introduced thus:

I take a small piece of screen-wire about 4 inches square, turn down about 1/4 of an inch all around the edge and insert it in a frame of the drone-brood and honey, and put the queen and a few bees between the comb and the screen. I let her stay there 10 days, at which time I liberated her. When I took the cloth off I found an empty cell had a larva in it. For the first time with me in introducing a queen in that way, the bees immediately killed the queen. The reason I know it was she, her wing was clipped.

Well, I thought them worthless, as there were no drones flying, and no honey or pollen for the bees to get, so, as I thought the colony was no good, I decided to put a new colony in the old hive. So yesterday I cut a fine bee-tree and thought I would burn up this drone colony, take the bees out of the tree and put in it. I hived my bees in a sack, brought them home, and built a fire to burn the drones, as I thought. I began to take out the frames and burn the bees. I burnt those from the first three combs, and to my surprise the fourth comb was well filled with brood and had a nice laying queen on it, and no drones in the hive. Now, how do you account for this queen? Of course she must have been reared from those eggs that were laid by the queen I tried to introduce, and she must have been mated to one of those drones that were laid by the infertile queen, as there are no drones at this season of the year, only in such a queenless colony. There is no brood here in the hives in November and December.

Will some of the expert bee-keepers tell how that queen was mated? I will be

pleased to hear from them, unless she mated with the unfertile queen's drones.

The reason I hive bees out of a tree in a sack is, they are more easily carried out of the mountains. As we often have to carry them miles afoot or on a pack-horse, a hive or box would be too unhandy. The mountains are full of bees. I found five bee-trees yesterday, and it was too cold for the bees to fly, and the only way I could find them was by knocking on the tree, or blowing in the holes. But it is hard work, as it is so rough and steep. From the tree I cut yesterday I got five gallons of honey and ten pounds of wax.

W. D. JEFFERSON.

Graham Co., Ariz., Jan. 27.

Wintering Well.

Bees have wintered well so far in the cellar. The new department called "The Afterthought" is a great improvement, for I think everyone will enjoy being "rubbed" after a little, after he takes his bee-medicine.

PAUL F. BRATZ.

Waukesha Co., Wis., Feb. 13.

Wintering Well—Prospects Good.

I have 30 colonies of bees in the cellar in good condition. I commenced with 24 colonies last year, spring count, and got only 500 pounds of honey. The prospects for the coming season are good.

RUFUS WILLIAMS.

Lawrence Co., Ind., Feb. 17.

Hard Freeze for Fruit.

We had a hard freeze here the first days of this month, which killed blackberry and raspberry bushes and nearly all larger fruit-buds; also killed a large percent of the prune, pear, and cherry trees. I think the prospect here for honey next summer is slim. This section of the State is not much for honey any year.

C. F. HOLT.

Marion Co., Oreg., Feb. 23.

Fear Winter Losses of Bees.

The recent cold weather (terribly cold weather prevailing here now) will, I fear, work havoc with the bees. Their winter stores are composed mainly of honey-dew and aster honey. The black stuff has a great tendency to sour in the combs, and there is a sticky, nasty oozing out upon the cappings that means almost certain destruction. Our winters here have been so broken that almost any kind of honey would winter bees, tho I much prefer good, well-ripened honey for them.

Scioto Co., O., Feb. 13. W. W. McNEAL.

Bee Mortality Not Great.

The weather has been very cold for more than two weeks, and bees have not had a flight since about the third week in January. The mercury has been below zero almost or quite every day for the last two weeks. Once it was 28 degrees below. Today it warmed up so that some bees flew at noonday. They made a heroic effort to clear themselves and also to clean house. The mortality does not seem to be great, but I never saw the snow spotted so badly. I am glad to say that the bees from one Tar Heel golden beauty, and one Buckeye State golden beauty, are standing the racket as well as any in the yard. These queens are going through their second winter.

EDWIN BEVINS.

Decatur Co., Iowa, Feb. 14.

Wintering on Honey-Dew.

I send you a small sample of honey-dew for inspection. My bees are wintering finely so far, eating that kind of honey and staying on the summer stands, without any protection except the single-walled hives; no losses up to this date, 90 colonies in all.

I took about 4,000 pounds of this sort of honey last year—some 600 pounds of comb

DR. PEIRO, 2nd Floor, Central Music Hall, Chicago, Ill.

Please mention Bee Journal when writing.

and the rest extracted. Everybody likes this honey in this part of the country.

This honey was produced by the small white aphid or plant-lice, of which there were multiplied millions to be seen on chestnut and oak timber through May and June. July was wet, and that put an end to the little "honey-distiller" for the summer, and that ended the honey-flow until September, when the bees gathered some nectar from the asters. A. J. McBRIDE, Watauga Co., N. C., Feb. 5.

Weather Severe on Bees.

It is quite severe on bees, just now, 32 degrees below zero and growing colder. My bees are in a cellar under the house, where there is no fire. The thermometer indicates 40 degrees; it has been 43 and 44 degrees all along until now. G. H. FREY, Linn Co., Iowa, Feb. 8.

"Good" Winter Weather.

We are having good winter weather here—now 32 degrees below zero. I am wintering one colony out-of-doors; they will think it a little chilly. I also have 57 colonies in a repository, which are doing nicely at 37 degrees above zero. C. E. TAYLOR, Ontario, Canada, Feb. 14.

Coldest and Snowiest.

Coldest and most snow here "within the memory of the oldest inhabitant." Would have to dig to find some of my hives. But as I am still shaky from the effects of the grippe, I can't get at them until the cold lets up. THOS. THURLOW, Lancaster Co., Pa., Feb. 15.

Pretty Cold Weather.

The very cold weather has kept me in the house, where it is warm, but as I have no rest in doing nothing, I have taken all my Bee Journals into the house (which are all bound in yearly hands—my own way) since 1880, wherein I find much, to me now, right and wrong. Some of the ideas and theories almost coax a smile out of a failing human. For the past ten days it has been from 20 to 40 degrees below, 30 degrees this a.m., 41 above in the bee-house, with a little gas in it. There is eight inches of snow on a level, making fine sleighing since Nov. 22. C. TUELLMANN, Wabasha Co., Minn., Feb. 13.

Cold Weather—Foul Brood Bill.

I think there will be a demand in this section for "Schmidt's Hardy Bees," if the present cold weather continues very long. It was 14 degrees below zero yesterday, with a strong wind from the northwest, and it was down to 23 degrees below this morning. I am writing to our representative today in regard to the Foul Brood Bill which we are interested in at present. JOHN S. DOWDY, Logan Co., Ill., Feb. 9.

Best Bee-Winter in Five Years.

As far as I know, this has been the best bee-winter for the five years I have had bees. Steady, moderately cold weather, and for the last 2½ weeks we have had zero weather constantly. Bees did only moderately well last year. Too many sunflowers, from which they gathered very strong and rank amber comb honey, which improves with age and keeps fluid in the combs. D. J. FRASER, Marion Co., Kans., Feb. 5.

Thinks It Very Cold Weather.

The weather has been very cold so far in February, the thermometer ranging from zero to 10 degrees below, with a piercing northwest wind which drives the cold

through almost everything except the fire. My bees have not had a good cleansing flight since the middle of November. I hardly know what condition they are in. It is too cold to think of opening hives to see, as they were all packed on the summer stands early in the fall, with plenty of good honey, and fairly well protected from the cold winds.

I had a fairly good crop of honey in 1898, mostly from buckwheat, which is all sold at a fair price. FRED E. WHITMORE.
Cayuga Co., N. Y., Feb. 13.

Something to Correct Fermentation

I think that boric acid is what Mr. A. W. Hart, on page 29, refers to, and I think he will find the article in one of the issues of the American Bee Journal of six or eight years ago, if my memory serves me rightly. That will not stop fermentation after it once sets in, but if put in while extracted honey is being cured, according to the article referred to, it will prevent fermentation. Extracted honey improperly cured, or, if properly cured, but stored in a damp place, is almost sure to ferment. The moisture should be well evaporated, and the honey then stored in a dry, warm room, and sealed in air-tight cans or bottles.

I am not acquainted with the chemical properties of this acid; it may, for aught I know, be very poisonous, and require very careful handling. B. A. THOMPSON.
Middlesex Co., Mass.

Cold and Windy Winter.

It is intensely cold, 18 degrees below zero, this forenoon. It has been cold and windy for 10 or 15 days, which makes me hunt the stove. I have 60 colonies in my bee-cellar, snug and warm, and 13 packed out doors. I believe those in the cellar will come out far the best, as it has been a pretty cold and windy winter. F. C. LEFEVRE.
Adams Co., Nebr., Feb. 9.

Second-Hand 60-pound Cans for Sale Cheap.

We have another lot of about 150 second-hand 60-pound Cans, two in a case, that we offer, while they last, in lots of five or more cases (10 cans) at 40 cents a case, f.o.b. Chicago. They are in good condition. Better order at once if you want some of them. Address,

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, Feb. 16.—This month trade has been of small volume in comb honey, due perhaps to the extreme cold that has made transportation dangerous, we now look for a better movement; yet the season is drawing to a close, as after the middle of March there is practically none sold until the new harvest is ready.

Fancy grade of white comb, 13c; travel stained and light amber, 11@12c; amber and dark, 8@10c; candied and mixt colors, 6@7c. Extracted, white, 6@7c; amber, 5@6c. Beeswax, 27@28c. R. A. BURNETT & Co.

DETROIT, Jan. 2.—No change in supply of honey as to quality, but prices are somewhat lower than last quotations, viz: Fancy white, 13c; No. 1, 12@12½c; fancy dark and amber, 9@11c. Extracted, white, 6@7c; dark, 5@5½c. Beeswax, 25@26c. M. H. HUNT.

INDIANAPOLIS, Jan. 4.—Fancy white comb, 12@12½c; No. 1, 10@11c. Demand fairly good, Dark comb honey is being offered at 8@9c with almost no demand. Clover and basswood extracted, 6½@7c. Beeswax, 26@28c. WALTER S. POWDER.

NEW YORK, Jan. 20.—Fancy white, 12c; No. 1 white, 10@11c; amber, 9c; buckwheat and dark, 7c. Extracted in good demand at unchanged prices. Beeswax rather quiet 27@28.

Trade in comb honey is quiet. White is pretty well cleaned up, but there is a large stock of buckwheat, amber and mixt, having accumulated of late, and in order to sell in quantity lots it is necessary to shade quotations. HILDRETH BROS. & SEGELKEN.

SAN FRANCISCO, Feb. 8.—White comb, 9½@10½c; amber, 7½@9c. Extracted, white, 7@7¼c; light amber, 6½@6½c. Beeswax, 24@27c.

Market is not favorable to buyers, more especially for desirable extracted, stocks of which are decidedly light. Comb is in moderate supply, and has to depend almost wholly on local custom for an outlet. Quotable rates remain as previously given.

BOSTON, Feb. 8.—The demand for comb honey is very light, with full stock on hand. We quote our market: Fancy white, 13@14c; A No. 1, 12c; No. 1, 11@12c; light amber, 9@10c. No demand for buckwheat. Extracted, white Northern stock, 7@8c. Beeswax quiet at 27@28c. BLAKE, SCOTT & LEE.

KANSAS CITY, Jan. 25.—Fancy white comb, 13c; No. 1, 12c; amber, 11c; dark, 10c. Extracted white, 6c; amber, 5c; dark, 4½c. Beeswax, 25c. C. C. CLEMONS & Co.

BUFFALO, Feb. 24.—Closely cleaned up on fancy one-pound combs; such kinds move brisk to-day at about 12 cents. Other grades have cleaned up mostly, but few remaining which are selling at 9c down to 7c. Extracted honey not much used here; stray lots 5@6c. Fancy pure beeswax, 30@33c; common, 22@28c. BATTERSON & Co.

CLEVELAND, Jan. 2.—Fancy white, 13@14c; No. 1 white, 12@13c; A No. 1 amber, 10@11c; No. 2 amber, 9@10c; buckwheat, 8c. Extracted, white, 7c; amber, 6c; buckwheat, 5c. A. B. WILLIAMS & Co.

MILWAUKEE, March 2.—Fancy 1-lb. sections, 13@14c; A No. 1, 12@12½c; No. 1, 11@12c; dark or amber or old, 7@10c. Extracted, in barrels or kegs, white, 7@7½c; dark, 5½@6½c. Beeswax, 25@27c.

Since our last report we have had a very good market for honey, and the demand has been very good for all grades, especially for sections of the best quality, and the demand is good now and small supply. We encourage shipments of best comb. Extracted, fair demand. A. V. BISHOP & Co.

Convention Notice.

Utah. The Utah Bee-Keepers' Association will hold their regular semi-annual convention April 8, at 10 o'clock a.m., in the city and county building, Salt Lake City. A full program in the interest of the industry will be presented, and all bee-keepers are cordially invited. Among the subjects to be considered will be the purchasing of supplies, the disposal of our products, and the best method for the protection of the industry. It is desirable to have every county represented, either personally or by letter. Questions are solicited. Mill Creek, Utah. J. B. FAGO, Sec.

Order Early

There are indications that the demand for SUPPLIES will be very large this season, and everyone should order as early as possible. We have large facilities for manufacturing all kinds of

Bee-Keepers' Supplies,

And will serve our customers as quickly as possible.

CONVENTION PROCEEDINGS

Report of the Chicago Bee-Keepers' Convention.

BY A SHORTHAND REPORTER.

The second quarterly meeting of the Chicago Bee-Keepers' Association was held Dec. 1, 1898, with a good attendance.

President C. Beers called the convention to order, and Secretary Herman F. Moore read the following paper by Hon. R. L. Taylor, of Michigan, on

Foul Brood in a Nutshell.

Foul brood is a term that is applied to a disease that attacks the larvæ of the honey-bee, and is attended with fatal results either before or soon after the cells containing them are capped. Unless remedial action be taken it generally results, in the course of a year or two, in the destruction of the colony attacked, not so much on account of the numbers of the larvæ destroyed as on account of the fact that from the consistency of the dead larvæ the bees cannot remove them, and so are precluded from rearing young again in such cells.

ITS CAUSE.

The disease is caused by the action of a microscopic organism termed "bacillus," from its rod shape. So far as I am informed its *nidus* or original home is not known, and the disease is spread only by the conveyance of the bacilli from one colony of bees to another.

HOW TO DETECT IT.

The healthy larvæ are of a glistening white color. When attacked by the disease they lose this lively appearance, and turn brown like coffee prepared with milk, when each is a homogeneous, glue-like mass. Now it is viscid or ropy, like mucus, as readily appears by inserting the end of a sliver in it and withdrawing it. This is the surest test of the disease, and for the greater part of the year the easiest to be applied.

This ropy mass after a time dries down and becomes a thin, dark-brown scale, lying on the lower side of the cell and reaching nearly, but not quite, to the open end of the cell. By holding the comb at the right angle in the light, these scales are readily seen, thus revealing the disease in the winter when there is generally no dead larvæ remaining in a viscid state.

Further, the cappings of comb much diseased are generally to a degree ragged, sunken, perforated, and discolored. The odor of a brood-nest much diseased is always bad, tho not always very strong, and will not be confounded, by any one having a good sense of smell, with anything else in the apiary, unless it might be with a bad case of dysentery.

Finally, a diseased colony has often its alighting-board near the entrance more or less bedraggled and dirty.

HOW IT SPREADS.

I speak not as a scientist nor as a microscopist, but from observations made during the practical handling of this disease. The bacilli multiply in the viscid matter of the dead larvæ, and the bees, in their efforts to remove the matter, get them upon their tongues whence they are conveyed to the cells of honey and then into the food of the larvæ. Sometimes, too, honey is stored in cells with the dried matter, which being thus moistened releases the bacilli so that they mingle with the honey. Of course, when such honey enters into the food of the larvæ they are pretty sure to contract the disease, and when such honey is carried away by robber-bees the disease is spread to new colonies. In endeavoring to control this plague, robbing in all its forms is the great thing to be guarded against.

HOW TO CURE IT.

Three days of comb-building with no brood to feed and no comb for the storage of honey, except what is made

R. L. Taylor.

within that time, frees the colony subjected to these conditions from all germs of the disease. The comb may be built either entire or from foundation. The problem then simply is, to put the bees under those conditions without permitting any robbing, or what amounts to the same thing, the mingling of any of the bees of the diseased col-

ony with other colonies. Practically, too, the prevention of robbing means the destruction of the identity of the combs and honey of the diseased colony by burning or boiling.

As comb-building is necessary for the cure, the best time for effecting it is during a honey-flow; and for the benefit of the novice in apiculture, I may say, also, and in conclusion, that the only time allowable (generally late or early in the day) for putting the bees under the conditions spoken of so as surely to preclude robbing, is when no bees are on the wing in the open air at all. R. L. TAYLOR.

Dr. Miller—How many have had experience with foul brood? [Two had.] Would you be willing to state what your experience has been?

H. S. Jones—The experience I have had is not practically with my own bees, but with those of a neighbor. I was called upon a year ago to come and look at his bees; he told me he couldn't get them to work or do anything with them; they were in bad shape. I found several colonies had foul brood. I went to work to clean the hives for him the best I could with what he had there; he had 40 colonies about a mile and a half from my place. He had never got any comb honey, and didn't know anything about it; the bees were let go winter and summer; I cleaned the hives up as best I could, and as far as I know they are in the same condition to-day that they were then; that was a year ago last summer.

Pres. Beers—He still holds the bees there?

Mr. Jones—Yes, and takes no care of them.

Dr. Miller—What did you accomplish by cleaning them up?

Mr. Jones—He saved several colonies.

Dr. Miller—How did you clean it?

Mr. Jones—I dumped out the hives and started the bees on fresh foundation.

John Eenigenberg—I found some foul brood this fall in one of my colonies; I think there are some more pretty bad, too. I weighed the colonies before I put them in winter quarters, and they weighed 35 pounds each; and when I examined them they were just full of foul brood.

Pres. Beers—Have you done anything with them?

Mr. Eenigenberg—I burned them, bees and all.

Dr. Peiro—From my information, the gentleman's treatment is very heroic, but I want to know if there is any other way it can be done. If you attempt to save the bees, they may contaminate the others and this foul brood infection may be imparted to the other colonies.

Dr. Miller—One of the first questions that I would probably answer is, Is it worth while to take up time discussing foul brood where nineteen-twentieths have had nothing to do with it, and don't care two straws whether it is foul or clean brood? Perhaps under ordinary circumstances I should say it is waste of time, but I don't believe it is in this case. It is time you did know about foul brood; it is the severe scourge—the one danger you have to face that will make you wish you never had anything to do with bees at all, and you would better know something about it; we should understand something about what the thing is; the paper that has been read on foul brood here this morning is a good paper; I don't believe that there was ever written a paper that covered as small a space, and contained as much information about foul brood, as this one. Suppose you think of a lot of thistle-seed scattered over your field—what are you going to do about getting rid of it? You can take up the root, but in spite of that the seeds are scattered over the ground, and, do what you will, it will come up again. Please understand this: Bacilli are simply little plants, and the spores are the seeds of those plants. Don't think as I thought a good while ago, that they are little animals, or something of that kind; they are little plants, and if you can kill all the plants and all the seeds then you are rid of the disease. Dr. Peiro asks very pertinently the question, If you save your bees, will they not still have those seeds and distribute them around? Those seeds must come into the proper place to grow. You can have thistle-seeds and carry them around in your pocket and they will do no harm, but put them in the ground and they are a most mischievous thing. The foul brood seeds must come into the larva; the bacilli may be more or less in bodies of bees possibly, but if you stop their being in the larva, you stop the whole business. The treatment is to throw your bees upon foundation and take away all the honey from them. That honey is contaminated, and it must not be used. Take a single drop of honey that comes from a foul-broody colony and it may cost you a hundred dollars, because you get the seed there. When you put your bees on foundation you understand they are not at that time having larva; they have perhaps in

their honey-sacs some contaminated honey that is used in comb-building or for their own use. If you are going to keep bees I advise every one of you to get Dr. Howard's little book on foul brood (price 25 cents), and be ready for it; that 25 cents may do you a great deal more good than \$100 after your bees have the disease. As part of the treatment is to throw them on empty frames, or nearly empty frames for the second time, everything they build has to be built fresh, and by that time all spores and plants have gone, and they are clean and pure, and you are rid of the disease, so far as that colony is concerned.

Mr. Eenigenberg—What would be the best season of the year to do it? The busy time of the year when they are working they use up the honey, but it won't make much difference this time of year, as things are quiet; if you attempt to go through with the treatment in the busy season you will lose the use of your colony. Don't you think the spring would be best?

Dr. Miller—The spring would be better than the following fall; suppose however it was August or September, it would be a better time than the following spring, because you get rid of it that much sooner.

Mr. Moore—Do you have foul brood in your apiary, Dr. Miller?

Dr. Miller—I am sorry to say I was fool enough at one time to say that I had never seen foul brood, and I was not going to see it, and would not look at it when I had an opportunity to do so. I am older now and have more sense, and would examine it carefully. I have never seen a case of foul brood. I am trying to tell you what you ought to do; I have informed myself about it, and don't believe that foul brood could come in my apiary and make very great inroads without my being able to spot it.

Dr. Peiro—I am interested in this thing; my bees may never have foul brood, and I may never see it, but I want to know the very best information I can get. I consider the cost, danger of it, and all that sort of thing, and I am quite of the conviction that our friend has done the very best he can, to destroy the whole business; but why do it in the fall when the combs are full of honey; why not do it before, and save the bees trouble and yourself expense? I think now if my bees had foul brood I would burn them up.

Mrs. Stow—Do I understand that the full-grown bees do not have this bacillus? It is in the honey and brood, is it not?

Dr. Miller—In the brood, but not in the organism of full-grown bee. A microscopic examination shows it sometimes in the grown bees, but it will not perpetuate itself in that way; it must be through the larva. Dr. Peiro says he would go through the same process our friend here did, burn it. If I had a colony attacked with foul brood I would destroy the whole business, root and branch, because it would be running too great a risk; but if I had a whole apiary infected before I knew about it, then I would try the other measure.

Dr. Peiro—Why not destroy it before the combs are full of honey?

Dr. Miller—You will not notice it, probably, until they are fairly started in the spring.

Mr. Eenigenberg—I examined my colonies in the spring, then they were all right, and lately I examined them and found some foul brood.

Dr. Miller—The Irishman's rule in a fight is, when you see a head hit it. When you see a colony affected with foul brood it is time to get after it.

A. P. Raymond—In the paper read by Mr. Taylor, he has told us the symptoms of foul brood. I am inclined to think many people believe their bees have foul brood when they have not any. I had a long talk about this with Mr. France, State inspector of apiaries of Wisconsin. He told me in his travels over the State he didn't find many cases of foul brood among extensive bee-keepers, but among those who had a few and did not take care of the bees. He stated one instance. One day he called upon a man who was about to drive out of his place as he (Mr. France) was driving in. The man told him he had some foul brood; that he had half a dozen or more colonies; he said, "I don't think it is necessary for you to look at them; I am going to burn the whole business to-morrow morning; it is my intention to burn up the whole shooting-match." Mr. France told him that as long as he was there he would like to go in and examine the bees. So Mr. France went in and examined them, and the man drove away. This I think was quite late in the spring or latter part of the summer. He found one colony—a new swarm that had its hive full of comb; the entire contents had broken down and laid upon the bottom-board, bees and everything. Of course, they

were all dead, and there was a horrible stench. He examined other hives, and found there was no foul brood in the yard at all. He went into the house and wrote a message to this man, to be delivered to him when he arrived home, telling him he had examined the bees and found no foul brood, and recommended taking out the hive that had broken down and save the rest of the bees. Mr. France saved this man five or six colonies of bees. So, as I said in the first place, we would better be sure ourselves that our bees have foul brood before we destroy them.

Mr. Moore—Have you had foul brood, Mr. Raymond, in your own apiary?

Mr. Raymond—No, sir; as Mr. France told me, he did not find any foul brood among extensive bee-keepers.

Pres. Beers Principally among those who, in your opinion, are careless and do not pay much attention to their bees?

Mr. Raymond—I think many times, possibly, there is some trouble with bees, and their owners don't know what it is, and consequently they destroy the bees unnecessarily.

Dr. Peiro—Mr. Raymond's suggestion is a very good one. After all there is an intrinsic evidence in foul brood, and I suppose that any person knowing it can't go wrong; that is, the condition of the cells, and especially the condition of the advanced state of foul brood. As stated in the paper, it looks like coffee that has had milk in it and that is sticky; stick a sliver in it and it pulls out like thin molasses; now if that exists, why, I don't think I would hesitate very long to surmise it was foul brood, and destroy it.

Mr. Richardson—I would like to ask if there is any work giving a history of this parasite?

Dr. Miller—Dr. Howard's book gives more than you will get from anything else. [This book is mailed from the office of the Bee Journal for 25 cents, or sent with a year's subscription to the Bee Journal—both for \$1.10.—EDITOR.]

(Continued next week.)

The Afterthought.

The "Old Reliable" seen through New and Unreliable Glasses.
By "COGITATOR."

TOO RESPECTFUL TO A CROSS COLONY.

Mr. Miles, you have written a first-rate article, and I guess you are all right, but it sounds almost as if you were too respectful to that extra-strong and cross colony you are preparing for cellar, on page 66. I was going to say, end the terrible tension at once; borrow a big cannon and blow the whole thing from the muzzle of it; but on the whole I won't say it. Under some circumstances your precautions are probably all right; only do not get our young brothers too much frightened before they are hurt any.

PASSAGE UNDER THE HIVE DISGRACEFULLY SATISFIED.

Mr. Pettit's contention, on the same page, that a passage under the hive is better than the bottom off entirely well, it may be correct, but Cogitator came through it without feeling that it had been proved exactly.

One gem of a thought that sparkles at the end of Pettit's article is where he tells us that the worst feature of the wintering situation is that so many are *satisfied*—satisfied with disgracefully imperfect results. Right he was, that time.

"TATER" DREADS TOO BIG SWARMS.

Mr. Coverdale, page 67. Too big swarms that have to be "scattered among all nations" before they will stay any place. Yes, Cogitator is aware that there is such a thing. Even a seven-pound swarm should have a little extra thought and care—and room. And a ten-pound swarm "Tater kind o' dreads.

ENTRIES FROM "RECORDING ANGELS" NEEDED AS SAMPLES.

So this is Aikin's way of recording: "4-1; 3-2-4." Which same means: April 1st, 3 frames, would hold all the bees; 2 frames would hold all the brood; 4 frames would

hold all the honey. Just to be hateful, Cogitator will complain that this doesn't look like an actual record. Two frames of brood too much to expect April 1st, of a colony only covering three frames.

Here is an actual entry from my own "Stand Journal": "5-4 Bees (12) Brood (38) Hon. (F. P.)" This reads: May 4th, bees 12 counts, brood 38 counts, honey enough for the present. Of course F. P. are the abbreviations of "for present," capitalized for convenience and prominence in the book. A count of brood is a rude estimate of a quarter thousand, which would be a patch a little over 3 inches square, and I think of 3 inches when counting. Thus, 38 counts are expected to approximate 9,500 young bees; and the ease of reducing counts to thousands is a point in favor of the system. The counts of bees are (for convenience's sake) much less accurate; and I bear the fact in mind that weak colonies are likely to number less bees to the count than strong ones. Combs with only a few dozen bees on are counted nothing; combs with 200 or 300 count one; combs thinly covered count two; and combs well covered count three. Long practice makes the various counts come easy to me as I look through a hive. Bees (12) would be, two combs well covered, two thinly covered, and two combs with considerable bare territory.

If a number of "recording angels" would send in an actual entry or two, then perchance beginners in the r. a. business might choose an eclectic system, with good points from several, and faults of none. (Or would they do just the reverse of that?)

The weak point of the Aikin recording is that a progressive man will every now and then be making changes in his system; and ten years hence he will be unable to read his own records, they are so largely in the mind of the recorder. Mine are full enough and clear enough that another person could probably read my record-books—with some effort and study.

BRACING FOUNDATION WITH SPLINTS A TWO-PLANET CLIPPER.

I was much interested with Dr. Miller's method of putting brace splints on sheets of foundation, to prevent sagging, as given on page 70.

And so Ernest Root has been clipping queens 50 years. Well, well! case of transmigration; and he elipt the bees of some other planet 25 years before he came over.

DRONE-COMB OPPOSITE WORKER-COMB.

I guess the drone-comb opposite worker-comb (page 74, paragraph 3) is all right. The foundation was probably so heavy that the bees treated it just as they would a wax board—first left one side alone then leveled and propolized it, and later on made it a half-comb of drone-cells.

WAS IT A LONG-TONGUED WOODPECKER?

"Tater wants to know whether that woodpecker's tongue was long enough to reach half the honey in the hive, or whether his everlasting thump, thump, thump, caused the bees to quit work, and eat the honey up themselves.

OPINIONS SPLIT LENGTHWISE AND CROSSWISE.

Query 89 is bad because it has two very different meanings. Suppose all the respondents had answered with a simple "Yes." Then some readers would have understood that a well-qualified individual, in a good location, might go into bee-keeping expecting to make his whole living out of it. Others would have understood that any ordinary person desiring an occupation might safely do so—a very different affair. Saying "any one" when we mean "every one" is one of the perversities of the English tongue—yet so common that it cannot be ruled out altogether. As it stands, the respondents are split lengthwise by their opinions, and crosswise by the view of the question which they take. About 15 out of 24 seem ready to encourage a good man in a good place. Apparently no one of the 24 thinks that indiscriminate plunging into apiculture offers a livelihood.

ADULT BEES ARE POLLEN-EATERS.

I think the impression prevails very widely among us that adult bees pass a considerable portion of their days without consuming any pollen. On this account I would jog the reader's memory once more on Dr. Miller's article, page 84. The Dr. Howard who is there quoted is one of the leading authorities. If every bee he ever dissected had more or less pollen-grains within, why, then, our impressions had better be giving way. Evidence pretty strong like a minnow in the milk and our impression that the milkman is honest will hardly suffice.

MORE EGGS NOT ALWAYS MEAN MORE BEES.

One of the penalties of eminence as a teacher is that carelessness of speech cannot be tolerated. The "fierce light which beats about a throne" is not wholly fun for the throne occupant. On page 83, Mr. Doolittle remarks, "The more eggs the queen lays the more bees in the hive." At the time, and under the circumstances he is thinking of, this is measurably correct; but beginners and students are in danger of taking it as an axiom of truth. In their minds it may lodge in the shape that eggs laid by the queen are always developed into bees; and that is far from being true, if I have the right of it. The spring-dwindling colony can develop only a fraction of the eggs we see; and the nice patches of fresh eggs we see late in the fall, in normal colonies, are probably nine-tenths of them left to perish. A few days of cold rain in May will consign thousands of eggs to non-development. And whether colonies which might do better sometimes contract a vice of destroying eggs (just as poultry are known to do) is a matter which will bear some investigation.

A BATCH OF SHORT "AFTERTHINKS."

Forty colonies requeened with young queens, and not one of them swarmed, is an instructive item on page 84.

Average surplus of Colorado in an average season 12½ pounds, page 85. I wonder how near to accuracy they got that. It is not surprising at all, seeing how many people "keep bees" in a way to get (and deserve) nothing.

I would amend Miss Porter's removal of bur-combs and propolis lumps after uncapping by having the same done before uncapping.

Pres. Aikin goes rather beyond me in his directions for extracting honey in cold weather, but I guess he's right 24 hours of warm room, and the last hours 98 degrees or more.

Yes, Mr. Aikin, if you can get the foundation makers to "mill" foundation so it will hang the toughest way of the grain, and with sidewalls vertical, too, you will be winning a little gain for us unless you bother 'em so much that they put on another cent.

Curious that 14,000 melted-wax foundation presses are used in Europe, and none in this country and that style of machine once had a good start here, too. Colorado folks trying to start it again. "Tater doesn't believe they will succeed, altho he wishes them well. Seventeen dollars for a \$5.50 press shows that all the atrocities of transportation have not yet been overcome.

Never thought of it before that our editor is so wise because he's one of the Y's.

FOUL-BROODY COLONIES AND HONEY.

The proposed foul brood law, on page 88, seems to me one of the best yet suggested. But I wouldn't pay for colonies destroyed, except in cases where more than half the yard is destroyed. The increase value of the rest will be compensation. And I'd put the upper limit of compensation at one dollar. Very rarely the case that bees demanding destruction are really worth more than that.

It's a splendid and up-to-date idea to give foul-broody honey two short boilings rather than one prolonged one. (Page 89.) Damages the honey less, and makes a surer thing on the "varmint."

WAX RENDERING AND MELTING.

The Beckwith wax press and process, referred to on page 90, had best be copied, picture, article and all, in all the journals. Evidently the best thing in its line.

Very slow cooling of cakes of wax usually works well; and very rapid cooling will no doubt work fairly, if you see to it at once that the wax lets go of the sides.

WHERE STINGS DIDN'T STOP RHEUMATISM.

Page 94 scores a plain case where stings did not benefit rheumatism. That stings sometimes cure wonderfully, and sometimes do no good at all, seems to be the situation.

COGITATOR.

Langstroth on the Honey-Bee, revised by the Dadants, is a standard, reliable and thoroughly complete work on bee-culture. It contains 520 pages, and is bound elegantly. Every reader of the American Bee Journal should have a copy of this book, as it answers hundreds of questions that arise about bees. We mail it for \$1.25, or club it with the Bee Journal for a year—both for only \$2.00.

The Spring Management of Bees, Etc.

BY C. P. DADANT.

I HAVE been asked to answer through the columns of the American Bee Journal the following questions:

1. How do you manipulate your brood-frames in order to get the greatest amount of bees to the hive? In other words, tell us something about frame manipulation and its relation to successful apiculture.
2. If you have both combs and full sheets of foundation, which would you use to hive swarms on, and which for extracting?
3. What are the dangers to a beginner in feeding bees?

P. D. GRAY.

The first and third of the above questions have a very natural relation to each other, so I will speak of these two first, and will afterwards consider the second question, which has no bearing on spring manipulation.

In the manipulation of hives in the spring there are two very distinct methods which ought to be considered comparatively and also separately to get into the details. The first method consists in allowing nature to work without any interference, except as it is absolutely necessary, in case the bees are short or weakened by circumstances beyond their control. This method is followed by the great majority of apiarists, but is certainly not always the most successful. The other consists in helping the bees in every possible way, by furnishing them whatever will tend to increase their activity and their prolificness; supplying them with food, extra space, additional shelter in cool nights, etc.

The first method is perhaps the safer one for beginners who are apt to overdo their part when manipulating the hive, and carry things to any extreme, which may prove even worse than a complete indifference to the condition of the bees. With an absolute lack of care certainly many colonies will suffer from want, or from extreme winter losses, and the loss in colonies will be great in hard seasons, after protracted and severe winter weather, or in cold, backward springs; but an experienced novice may lose as many bees through over-management as through entire indifference. In any case, it is entirely indispensable to ascertain early in the spring the needs of each colony.

The first requirement is a sufficient amount of stores to breed and recuperate winter losses to all colonies having laying queens. Queenless colonies need but little feed, as the brood consumes much more food than the adult workers. Then a queenless colony is less able to defend itself than one in normal condition, and is more likely to get robbed. So it is hardly advisable to feed them unless they are entirely destitute, or unless they have been given brood for queen-rearing, and are in a fair way to recuperate. But queen-rearing in this climate can hardly be attempted till April 1, and in the meantime such colonies must remain in *status quo*.

The apiarist who wishes to carry his bees through with the least possible expenditure of time will ascertain that all the colonies have a sufficient amount of honey, and not too great a breeding-space, and will then leave them to their own resources until the beginning of bloom. If this method is not a very forcing method, it has at least the advantage of not taking any risks of drawbacks and reverses through artificial forcing, when there is still a possibility of severe weather which might chill the brood of a too precocious colony. Yet, even with this method it is not advisable to leave four or five empty combs in a hive if there is only about the same number occupied by the bees. A large, cold space in spring is sure to delay the breeding, and here the division-board, or dummy, plays an important part by enabling the man who wants to succeed to reduce the space within normal limits, making a small colony as comfortable in its hive over the space it covers as a larger colony may be in a greater compass. Two or three, or perhaps four, visits to each colony during the spring will enable one to readily follow the progress of the bees, and enlarge their space as needed, wherever weak colonies have been found towards the close of winter.

But if an apiarist has the leisure to attend to his bees daily, or if he is making it his especial business to rear his colonies to the highest possible strength for the honey harvest, there is no doubt that he can achieve very much more,

and secure enough more honey to pay him for his extra pains, if he more closely attends to their needs. But, as I said before, it would be a great mistake to recommend this practice to the beginner, as he would perhaps overdo his work, and make a failure of his very eagerness for success. With this warning I will proceed to map out the course that may be successfully pursued.

As early as convenient, provided the weather is suitable, an examination of each hive is made, dead bees removed, and all weakened colonies reduced to not over two combs more than the entire number they cover. The weaker the colony the more closely confined it must be. If upper ventilation has been furnished during the winter, and there is no probability of very hard freezing weather, it is best to close up all upper currents of air, for these have been given in the first place, only to prevent the gathering of the moisture over the combs during frosty weather. This moisture is no longer to be feared, but the air-current takes away heat, which is very necessary to the rearing of brood. So we close all upper currents and still retain as warm a covering as possible, and all the shelter that is available. The entrance of these weak colonies is reduced to a mere fraction. It must be of easy access, but as small as practicable. If feed is needed, and the weather is likely to be cold, so as to make it inadvisable for the bees to stir about, it is best to feed by supplying honey in the combs by interchange with more wealthy colonies. If the weather is fairly warm and likely to remain so, a little warm feed, but only a little at a time, is given right above the brood in a place of easy access.

Mr. Gray, in the questions asked above, refers to the dangers to a beginner in feeding. He has evidently "been there," and is not himself a "beginner." This early feeding of weak colonies is a stone in the path of the apiarist over which he will surely stumble, if he is not very cautious, as can probably be testified by hundreds of my readers. When we supply the bees with combs of honey sealed, and in good shape, there is no excitement. In a few minutes they have taken possession, and see no need of hurrying to consume it. But when warm feed is given it acts upon them exactly as a crop of honey would that began all of a sudden. They become so elated by their "find" that they lose all restraint, care for nothing, but spread the good news abroad, and not only stir up their own colony to unexpected activity, but even seem eager to spread the news to the neighborhood, and "gossip" it about from door to door, apparently, but in reality imagining that they may expect to find good things almost anywhere.

If the weather is cold, many bees will perish that have strayed too far away. If it is warm the buzz and excitement may attract some powerful neighbor, that will at once think of "expansion," and will try to annex the supplies of its weaker acquaintance. So it is necessary to keep a close watch and to use considerable discernment in the feeding of fresh food to weak colonies. Hancock Co., Ill.

(Concluded next week.)

Annual Report of Ontario's Inspector of Apiaries

BY WM. M'EVROY.

DURING 1898 I visited bee-yards in the counties of Essex, Middlesex, Huron, Grey, Wellington, Simcoe, Cardwell, Norfolk, Wentworth, Lincoln, Peel, York, Ontario and Victoria. I examined 100 apiaries, and found foul brood in 32 of them.

Nearly every bee-keeper that had foul brood in his apiary wrote me private letters about it, and, working on the rule of doing to others as I would like to be done by, I treated all such letters as if they were marked strictly private, and always will. By working along this line in a quiet way, and helping the owners of the diseased apiaries to cure their colonies, I have been able to find out more about who had foul brood in their bee-yards than could, or ever will, be found out in any other way.

I am very much pleased with the way the owners took hold and cured their apiaries, and particularly so with two that were cured by two ladies in the county of Simcoe. These two ladies did the best work in the shortest time that I ever had done, and with two of the worst foul-broody apiaries I ever handled.

Scarcely one week ever passes any more than I do not receive more or less letters asking questions about foul brood, and dead brood of other kinds. I have also received very many samples of combs with dead brood in them, and about seven out of every ten of these were genuine foul

brood. The most of the letters, and samples of comb containing decayed brood, came from many parts of the United States, and the others from bee-keepers in the Provinces of Ontario, Quebec and Nova Scotia.

"About how long would foul brood be in a colony before it would become very bad with the disease?" was one of the questions asked by several of the writers. I answered, saying, sometimes not more than one week; in others over one year; but in the most of cases less than three months. Just how soon or how long it would be before any diseased colony would become very bad with foul brood would depend entirely upon how much, or how little, of the honey was diseased. The honey to become diseased must be stored first in cells where foul-brood matter had dried down, and when any honey is removed from such diseased cells, to cells partly filled with sound honey, it will disease it also. Foul brood is spread through a colony just in proportion to the amount of diseased honey that is fed to the larvae.

I sent out Mr. F. A. Gemmill a part of the time, and he inspected 15 apiaries, and found foul brood in three of them. I am very much pleased to say that neither Mr. Gemmill nor I had to burn one diseased colony. We found all parties very willing to cure, and gave them a chance to do so.

I believe that the Province of Ontario has less diseased apiaries for the number kept than any country in the world, judging by the number of letters that I have received.

For the very nice way that Mr. Gemmill and I have been treated by all parties while on our rounds through the Province, we return to them our most heartfelt thanks.

Woodburn, Ont., Canada.

No. 3.—Doolittle's Talk on Bees at a Farmer's Institute in New York State.

BY REPORTER.

(Continued from page 147.)

HE next took the grains in a like manner, showing that buckwheat was the only grain raised in central New York which needed the aid of the bees, and that was the *only* grain that secreted nectar, yet time and again had jealous persons claimed a remuneration from him for the damage done their buckwheat yield, by the bees taking away the nectar needed to bring the grain to perfection! But with the farmer who had kept a record of his yields of grain from buckwheat, he had always been able to show him his mistake, by comparing that record with his honey record, so convincing the farmer that in the years of his greatest yield of buckwheat grain, Doolittle had secured his largest yields of buckwheat honey, and *vice versa*.

He then took garden truck, speaking of the vine family, and proved from Gregory, the great squash-raiser, how it was an impossibility to secure even an *imperfect* squash, pumpkin, melon or cucumber from any female blossom where bees had been excluded from the blossoms by tying netting over them as Gregory had done in his experiments at cross-fertilization, unless fertilization was accomplished by the hand of man. His reasoning was so conclusive that many changed their views entirely, as was admitted by several to the writer, and from the energy Mr. Doolittle put in this part of his address it was very evident that herein lay the main object of his coming. But as before, he must clinch the point with a story which ran as follows:

A certain farmer dreamed he died and went to hell (not that all farmers go to that place). And when he arrived there, an imp from the Satanic majesty met him to escort him around "sight-seeing" before he took up the place of his final abode. He took him first to a room in which were many politicians, all writhing and crying out in the terrible burning, which made the farmer shudder and draw back. Then to a place filled with lawyers burning in like torment. Next, to a place where there were brewers, distillers and saloon-keepers, where it appeared, if such a thing was possible, that the "burning" was hotter than any other. Then to where there were mechanics, then merchants, then a few ministers, who had mistaken their morality for the new birth; and church-deacons and members who had used their profession as a cloak to cover iniquity—all of whom were suffering such excruciating torment that the farmer was sickened in the extreme, and was about to say he had seen enough, when it came to him that he had seen no farmers in any of the places he had visited. So he inquired if there were any farmers that came there.

"Oh, yes, plenty of them," was the reply. "Would you like to see them?"

Assenting, he was taken to a room which was very hot, but in which there was no flame to be seen. To the ceiling of this hundreds of little turn-tables were fixed, which were slowly revolving around, while to each of the turn-tables was affixed the feet, or heels, of a farmer so that he hung head downward, slowly revolving in space, in that awful heat. The farmer appealed to the imp to know what it all meant, and was met with the reply that "the farmers when they came there were very 'green,' so much so that they had to be hung up in this way and be kiln-dried before they would burn!"

At this point the audience broke entirely away from the speaker, and for fully a minute went wild with laughter and applause, which was evidently "too previous" to suit him, as what he wished to enforce more particularly was lost sight of in the merriment, as the point was forgotten, or failed to impress, through the ridiculousness of the story.

As soon as any degree of quiet could be restored, Mr. D. gave the "point," which was the finishing of the imp's speech, viz.: "Why, the farmers are so green that they would kill their best friends, the bees, by spraying their fruit-trees while in blossom."

Continuing, Mr. D. said: And now, in conclusion, I wish to say a few words which will not only apply to bee-keeping, but to all the pursuits in life. To be successful in the highest sense of the word, a person must *love* his occupation far beyond the dollars and cents which may come through it. I have been a careful observer for many years, and I have yet to see the person who makes a success of any business upon which he entered, when such was done wholly and simply to make money out of it. No, no, there is no success, either financial or otherwise, when the only thought which enters a person's being is *money getting*. We must love the bees until we see only *fun* in our work with them. We must love our horses until it is only *sunshine* to care for them, and see that they are comfortable. We must love the cows till an hour spent in their society is more precious to us than an hour spent at the corner grocery, listening to the idle gossip there, and the same with all our farming operations.

I have been keeping bees for 30 years, and still stings, sweat and toil are only pleasure to me, except the extreme pain for the first few seconds after being stung. Mrs. D. says I care more for the bees than I do for my dinner, any day. For often it is from five to fifteen minutes before I can tear myself away from them to go to dinner after she has called. And some of these cold winter days I go poking around to get even a glance at the pets, when attending to other parts of the business would be more to their advantage and mine.

I have listened carefully to all of the speakers who preceded me, and very little has been said except for the *profit or money* side of farming, poultry-raising and dairying, as if that were to be the chief objects in life. I wish to counteract that thought. The money-getting part should be secondary. "Seek ye first the kingdom of God, and then all these things shall be added." But I confess we are all built very much on the plan of the crane in the ancient legend. A beautiful white swan alighted on the banks of the water in which a crane was wading about among the reeds and rushes seeking snails for his breakfast. For a few moments the crane viewed the swan in stupid wonder, and then inquired: "Where did you come from?" "I came from heaven," replied the swan. "And where is heaven?" asked the crane. "Heaven," said the swan, "Heaven! Have you never heard of heaven?"

And the beautiful bird went on to describe the grandeur of the Eternal City, the New Jerusalem. She told of the streets of gold, the gates of pearl, and the walls of jasper; of the river of life, pure as crystal, upon whose banks is the tree whose leaves shall be for the healing of the nations. How there was no night there, no sickness nor crying, for God shall wipe away all tears from all eyes. In eloquent terms the swan sought to tell of the hosts who live in the spirit world, but without arousing the slightest interest on the part of the crane. Finally, the crane asked:

"Are there any snails in heaven?" "Snails!" repeated the swan; "no! there are no snails there." "Then," said the crane, as he continued his search among the reeds and rushes of the pool, "you can have your heaven. I want snails!"

Let us get away from the idea that the snails of money-getting are all there is of life, for many a man has sacrificed all there is good in life in his search for snails. Many a man has sacrificed all the comforts of home, wife, family, in fact his all, for the snails of sin. Oh, let us get a broader view of life, a *love* for everything about us—a love which

shall give us more exalted views of life, and thus shall we be lifted to a higher plane, and as we are lifted up we shall draw others up, up nearer to God.

When Mr. D. had finished he was given another round of applause, after which W. W. Newman, the man who gave the address of welcome in the morning, moved a vote of thanks for the good way Mr. D. had entertained them. This was seconded by a half-dozen voices, when the Wisconsin governor arose and said he believed Mr. Doolittle had been wrongly named, that it was evident that he had *done* more than a *little*, and not only this, but that he had had many *little* helpers all along the way in his pursuit.

The chairman of the meeting then arose and said he had been greatly interested, and wished he could spend several evenings with Mr. Doolittle in talking bees, after which he put the motion, which was carried with much emphasis.

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[Questions may be mailed to the Bee Journal, or to Dr. Miller direct.]

Which Way Should Hives Face?

On page 117, Cogitator objects to my thinking there's no material difference between east and southeast as the direction for hives to face. Since he objects "respectfully," I'm willing to twist the hive that eighth of a circumference, but if I do that I'm afraid of getting into trouble with Editor Doolittle. In the last number of the Progressive Bee-Keeper he is very emphatic in preferring south to north exposure, especially if left on the summer stands through the winter. He says:

"Years ago I tried the experiment of facing a part of the apiary to the north, leaving them thus during the winter, and while those facing south had two or three good flights during the winter, and came out in good condition in the spring, those facing north flew scarcely at all, and all but one died before the next May; and even during the summer season, the hives having their entrances facing north would not start out to work in the morning for a long time after those facing south were fully started for the day. In every apiary which I have visited during my 30 years of bee-keeping, I have found the hives facing from southeast to southwest, the majority facing south, which is the correct way, where hills do not seem to make it necessary to vary a little."

Now there you are. Doolittle says south is the correct thing, practice of others varying from southeast to southwest, making sure in any case of having that 12 to 2 sun to which Cogitator objects. Now how am I to manage to keep friends with both those men? C. C. MILLER.

Feeding Syrup.

I have 10 colonies of bees to feed, and I have no honey to feed them. What would be the best way to feed sugar syrup?

ANSWER.—If they can stand it till time for them to fly every day or two, a Miller feeder or the crock-and-plate method will be all right. If they must be fed right away, it will be better to fill the syrup in combs, so you can put it right in the hive close to the brood-nest. Lay a comb flat in a tub, and pour the syrup, pretty hot, into it from a height of four or five feet, preferably using some kind of a dish that will let it fall in a lot of little streams. One way is to punch a lot of holes in the bottom of a baking-powder can or something of the kind, hold this at the proper height, then pour the syrup into it from a pitcher or other vessel.

Frost in Hives in the Cellar.

I looked at my bees to-day and found the hives full of frost, more on the rear end than on the other walls. Some were completely covered with a coat. I should judge, from $\frac{1}{4}$ to $\frac{1}{2}$ inch thick, but where the bees were there was no frost. I scraped out the dead bees, which were not so many as I expected. I put my 18 colonies of bees in the cellar, 16x16 feet, when cold weather set in. The entrances of my hives are small; since reading the Bee Journal I found they were too small for any use. I have nothing in the cellar

but bees, and the temperature has been too low to be good, but it was impossible for me to keep it warmer. I am afraid when warm weather comes, and the frost melts, the bees will get wet and damp, and perhaps die. WISCONSIN.

ANSWER.—It is quite possible that no great harm may come from the frost in the hives, if it is only on the sides and not directly over the cluster of bees. But a cellar that is so cold as to let frost gather in that way in the hive is not a fit place to winter bees. Can't you heat up the cellar in some way for a few hours? If there is an inside door connecting with the kitchen, leave that open at night, keeping a good fire in the kitchen. If you can't do that, take down some heated stones or iron, or take down jugs of hot water. But don't try hot water unless tightly corked so steam cannot get out. A stove with fire in it would be the thing, but it isn't likely you can have that. If the bees are uneasy and spot their hives with diarrhea, take them out the first day warm enough for them to fly, say on a bright day with the thermometer at 45 or 50 degrees.

Swarms from Clipt Queens.

Should two swarms issue from hives containing clipt queens at the same time, and cluster on the same place, on returning to the hives, would they all return to one hive, or go to the hives they came from? ILLINOIS.

ANSWER.—Generally they go back to the same hives from which they came, but sometimes all go to one hive. Sometimes they will do neither, but go to some other hive where there is a big commotion because of swarming a short time before.

Worms in Hives—Eight-Frame Hives.

1. I have some bees in box-hives. I lost one colony last fall with worms; how do you clean them out, and when is the right time?

2. I expect to use the 8-frame dovetail hives next season. Do you think the bees will winter in them on the summer stands? The thermometer gets as low as 15 or 20 degrees below zero. NEW JERSEY.

ANSWERS.—In box-hives you must depend upon the bees to clean out the worms, as there's no way you can get at the combs to dig out the worms. Strong colonies will not allow them to make great headway, especially if the bees are Italian.

2. Very likely they will winter all right, but 10-frame hives will be safer, for colonies are likely to be stronger and to have larger stores for winter. In either case they should have some protection for winter.

Moving Bees—Using Queen-Excluders with Sections.

1. I have bought a place and will have to move my bees about 2½ miles. Which do you think is better, to take them right out of the cellar and move them, or set them out in the yard and let them have a good flight, and then move them?

2. What do you think of using the queen-excluding zinc with sections? I thought some of trying it with a few hives, and giving them sections about the second or third day after hiving. My object in doing this is to give them lots of room in order to prevent swarming. WISCONSIN.

ANSWERS.—1. Decidedly, let them have a flight before hauling.

2. Under ordinary circumstances there is no need to use a queen-excluder with sections, but it's a good thing to do so when sections are put on immediately after hiving. But there is no danger of bees swarming within some time after being hived. Your idea is all right, however, to give plenty of room in supers.

A Queen Rearing Drones or Workers First.

Would a queen that was superseded late in the fall, after the bees ceased flying, be likely to rear first drone or worker brood, and why?

Case: A colony of blacks was transferred late in the fall, and after some weeks a weak queen crawled out of the hive, was picked up, and soon died. Early in the spring a brood was noticed and thought to be from laying workers,

as no queen could be found. On introducing a new queen a black one was found in the hive, and captured. The introduction was not a success, and in taking care of the frames a cluster of worker-brood was found on the same frame as the drone or supposed laying-worker. I have thought perhaps the queen was not fertilized, and her first duty was to rear drones for that purpose, hence my question. MISSOURI.

ANSWER.—Whatever a queen might think about it, she never would be fertilized by a drone of her own progeny, for after she commences once to lay she will never be fertilized afterward. If reared in the fall, she might be fertilized in the spring, and then would be likely to lay the same as any other queen, principally worker-eggs.

Taking Bees Out of the Cellar for a Flight.

I have 75 colonies of bees in the cellar. They were all right up to the first of this month, but now they do not seem to do well; the bees are dying fast, and the hives are dauby. Will it be better to take them out of the cellar as soon as the bees can take a flight, even if there is a little snow on the ground, or later?

We had honey-dew here last summer, and the bees got a lot of that stuff. It was the first time that I saw honey-dew in this place; but we get good honey here. In 1897 I got 1,925 pounds of comb honey from 16 colonies, spring count, which I sold at 15 cents a box. Last year there was no honey. I got only 1,500 pounds of fall crop from 30 colonies, spring count. MINNESOTA.

ANSWER.—Yes, I'd take them out for a flight the first day it's warm enough. If snow is on the ground it may be of some advantage to make some effort to keep the bees from sinking in it. If very little, the ground about the hives might be swept. Otherwise the snow might be tramped down hard, or something might be used to cover the ground, perhaps straw.

Transferring from a Box-Hive and a Tree.

1. I have a colony of bees in a box-hive, and I would like to transfer it into another hive. How shall I do it, and when?

2. I know of a colony in a tree, and I would like to take it home and put it in a hive. How can I go ahead with that, and when would be the best time? PENNSYLVANIA.

ANSWERS.—1. Directions for transferring are given in the text-books, and hardly belong in this department. You will probably be as well satisfied to wait till after the bees swarm, and transfer 21 days after the swarm issues.

2. It depends upon circumstances what is best to do. If other trees are near by, it may not be a hard thing to take the bees home in the log where they now are. By means of a rope you may ease the falling of the tree when you cut it down so that the combs will not be broken. Tie one end of a long rope to the upper part of the tree, throw the other end over some part of a neighboring tree, and then when the tree falls you can let it down gradually. Then cut off the log above and below where the bees are, haul it home, and you can transfer it when convenient, either before or after swarming.

Changing Location of Hives and Arranging Them.

1. When is the best time to remove bees from their usual place?

2. Have you any special method of removing colonies?

3. Is it best to have colonies widely separated, or in groups? KENTUCKY.

ANSWERS.—1. If their location is to be changed it is better to make the change before bees do much flying. If bees are moved after they have made well their location, they are likely to go back in considerable numbers to their old location. It will be some help, after they are moved, to put up before the entrance a board so as to hinder direct flight as much as possible.

2. No, just pick up the hives and carry to the new place.

3. There is some advantage in having them in groups, making it more convenient for the bee-keeper than to be obliged to travel over much ground. A good way is to have them in groups of four, one pair standing back to back to the other pair. A space of four inches is enough between hives, and four feet or more between groups.

United States Bee-Keepers' Association.

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., E. Whitcomb; Vice-Pres., C. A. Hatch; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GEN'L MANAGER AND TRASCURER—Eugene Secor, Forest City, Iowa.

VOL. 39. MARCH 16, 1899. NO. 11.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

The Dot Contest Prizes will have to wait another week, we regret to say, before we can close them up. We began to sort out those given to the Langstroth Fund from the others, and found it such a large job that we couldn't possibly get it done in time for this issue. But next week, even if we have to work all the nights between now and then, we will be ready to make a final report on them. The prize money has long been ready for the successful contestants, but the clerical work necessary to arrange the matter properly is more than we anticipated.

Apis Dorsata and the Government. Bion Walbridge applied to the Government to obtain some of the big bees that newspaper reports said would soon be introduced from the Philippines. The reply from Washington is published in *Gleanings*, and its main part is as follows:

The newspaper report which you mention was unauthorized. The Department has not, as yet, undertaken the importation of bees from the Philippines. Should they be obtained, however, they would first be carefully tested before any general distribution would be decided upon. If then the latter course should be deemed advisable due notice would be given to those interested, and your application would be favorably considered by the Department.

L. O. HOWARD, *Entomologist*.

When *Apis dorsata* arrives in this country it will very likely be promptly announced in the bee-papers. But it is very doubtful that they will be ready for general distribution among bee-keepers in this country before the Twentieth Century.

Publishing Post-Office Addresses of contributors to the columns of the Bee Journal is a practice we discontinued about two years ago. And we did it for very good reasons, too.

First, we decided that it was unfair to charge certain good people for putting their names and addresses in the advertising columns, and then in pure reading-matter putting the names and addresses of other people for nothing.

Second, we knew that many of our correspondents did not want to be pestered with a lot of letters from people they didn't care anything about hearing from. For instance, Mr. Stolley, who wrote on sweet clover recently, asked us to announce that he had no sweet clover seed for sale. But by omitting his full address, of course no one could well bother him. Once before, when he wrote on sweet clover, and his full address was given, he received many letters, and most of them from people who were unbusinesslike enough not to put in a stamp for reply, so Mr. Stolley was out his stationery, his time, and his stamps.

Third, if any one wants to do business through the Bee Journal he must pay for it. It costs money, and lots of it, to publish a paper like the Bee Journal every week, and it is only right that advertising should be paid for. The subscription price alone doesn't nearly cover the cost of getting out the Bee Journal.

Now, we trust that our readers will understand our position on this subject, and not keep on asking us why we don't publish the full addresses of our correspondents. Other papers can do as they like about this, but we propose to do the fair thing by those who pay us cash for putting their advertisements in the Bee Journal. We know that we have taken the right stand in this.

A Few Pointers on Foul Brood.—Mr. N. E. France, foul brood inspector for Wisconsin, sends us the following on the subject of foul brood:

"On page 90 is given G. Sawyer's method of curing foul brood, which is all right except that I object to burning anything containing foul brood upon the ground, but always in a pit on level ground, and the clean soil returned over the ashes. Foul-broody combs can be melted in boiling water and the wax safely used as comb foundation. If diseased honey is boiled in good earnest for 15 minutes, and stirred with a stick all the time (the stick then burned), the honey is safe to feed bees."

The Simplified Spelling of the English language is slowly gaining ground. For over two years we have been working on some words—using "t" for "ed" when the sound is "t," with a few exceptions; also *tho* for *though*, and *altho* for *although*. We think our readers are becoming familiar with this beginning, and will agree with us that it is time for us to make another advance in simplified spelling.

Mr. Irwin Shepard, secretary of the National Educational Association, sent out this notice last August:

ANNOUNCEMENT AMENDED SPELLING.

The department of superintendence of the National Educational Association, at its meeting in Indianapolis, Ind., Feb. 17, 1898, appointed a committee consisting of Dr. William T. Harris, United States commissioner of education, Washington, D. C.; Dr. E. Louis Soldan, superintendent of schools, St. Louis, Mo.; and T. M. Balliet, superintendent of schools, Springfield, Mass., to recommend a list of words with simplified spelling for use in the published proceedings of the department.

The report of the committee was duly made, and the spelling so authorized was used in the published proceedings of the meeting of the department held in Chattanooga, Tenn., Feb. 22-24, 1898.

At a meeting of the Board of Directors of the National Educational Association, held in Washington, D. C., recently, the action of the department of superintendence

was approved, and the list of words with simplified spelling adopted for use in all publications of the National Educational Association, is as follows:

Program for programme; *tho* for though; *alho* for although; *thoro* for thorough; *thorofare* for thoroughfare; *thru* for through; *thruout* for throughout; *catalog* for catalogue; *prolog* for prologue; *decalog* for decalogue; *demagog* for demagogue; *pedagog* for pedagogue.

You are invited to extend notice of this action, and to join in securing the general adoption of the suggested amendments.

We believe that we have always used *program* for programme in the Bee Journal, and *catalog* for catalogue, so there will be only about a half dozen more words that will require our attention, in order to be up with the National Educational Association. Next week we hope to begin on them, and trust that our readers will help on the good work all they can by also adopting the simplified spelling in their correspondence. It's a grand thing to be *leaders* in wise reforms, and we hope that bee-keepers will be in this one from start to finish.

How Much Honey at a Meal?—"Stenog," the new department editor of Gleanings, "touches us up" in this style on the subject of how much honey one can eat at a meal:

"It seems that Mr. York doubted whether three persons ever ate a pound of comb honey at one sitting. Mr. Murry says two often eat that much. Certainly why not? Evidently Mr. York can't bear honey as well as some of our human bruits can. I can eat half a pound of good clover honey at one meal any day, with impunity (or milk without the impunity). But I never eat on a wager, nor to show what I can do. I eat to live, and stop when I have enough."

This leaves one in confusing uncertainty as to the real honey capacity of "Stenog." Does he mean he *always* stops when he has had enough, and that half a pound at a meal is the proper allowance, if taken with milk or impunity? and if so, how much could he stow away at a meal if he could secure a fair wage for his labor?

Good Advice for all bee-keepers is given in this paragraph by Editor Hill, of the American Bee-Keeper:

If the young bee-keeper has not already done so, he should now begin to put everything in readiness for the coming season. The busy days will soon be here again, and our success will largely depend upon the preparation we have made. Like a colony of bees, the mind of the bee-keeper is often materially advanced by a little "stimulative feeding" in the spring, which is handsomely repaid in the season's results.

Mr. Hill also wisely recommends the reading of a bee-book as a "spring tonic." It seems a pity that any one should think of making a thorough success with bees without getting and studying one or more of the several excellent bee-books and bee-papers now published. It would be time and money well invested.

The U. S. Association, through its General Manager and Treasurer, Mr. Secor, is sending out notices of expiration of memberships. We received the following recently:

MY DEAR BROTHER BEE-KEEPER: The Treasurer's books show that your membership in the United States Bee-Keepers' Association is paid to Jan. 1, 1899. If the record needs correcting to accord with the facts, I shall be glad to be notified. If correct, I shall hope to receive the amount necessary to renew your membership to date, including the current year.

The Board of Directors have some work in view which is in the interest of the bee-keeping fraternity, but it cannot be prosecuted without the help of those whom it is intended to benefit. The membership fee is \$1.00 per year. It is hoped that all bee-keepers will feel so interested in the effort to protect the purity of honey, and, in fact, all bee-

keepers' rights and interests, that they will become members at once, if they are not already.

Fraternally yours, EUGENE SECOR, *Treasurer*.

The new plan of thus notifying members was recommended at the Omaha convention, and must prove a good thing for the Association, in keeping up the membership list. While now there are only about 400 members, there should be a full thousand, at least, so that the Board of Directors would feel more like undertaking some adulteration cases that ought to be taken up now and pushed to a finish. Everything is ready except the cash to go ahead with; and that must be supplied by the bee-keepers—those who are most interested in the enforcement of laws against the adulteration of honey.

JOHN NEBEL & SON, of Montgomery Co., Mo., have sent us their annual bee-supply catalog for 1899.

M. H. HUNT & SON, of Wayne Co., Mich., have issued their 17th annual catalog of bee-supplies, a copy of which is on our desk.

MR. WM. J. BROWN, of Skagit Co., Wash., writing us March 2, said:

"The Bee Journal is worth its weight in gold to a bee-keeper if he has the money to pay for it."

MR. GEO. I. WOLF, of Cass Co., Ind., wrote us March 7, when renewing his subscription for another year:

"I can't do without the American Bee Journal, for I have learned three dollars' worth from its pages so far this year."

MESSERS. R. H. SCHMIDT & CO., of Sheboygan Co., Wis., one of our regular advertisers, wrote us March 3:

"Business is good. We are also pleased to say that our bees are all in very good condition, and have had several good flights. We expect a rich honey harvest this year."

MR. W. S. PENDER, of the firm of Pender Bros., of Australia, is visiting in this country, calling on some of our principal bee-supply manufacturers and publishers. His own firm deals in bee-keepers' supplies, and does a large business in that far-away land. Mr. Pender is a very pleasant gentleman, and a thorough-going bee-keeper, having for several years edited the Australian Bee-Bulletin, now the only bee-paper in Australia, we believe. We trust that he will have a pleasant trip and safe return home.

ADVANTAGES OF DIRECT BUYING. Certain manufacturing institutions have in recent years inaugurated a new system of disposing of their products which is unqualifiedly to the advantage of the consumer. It took courage to make the change, but they did it. Among the pioneers in this new method of doing business was the Elkhart Carriage & Harness Mfg. Co., of Elkhart, Ind., whose advertisement appears on page 173 of this issue. These people began this plan of doing business 20 years ago, and have adhered to it strictly ever since. The result has been so entirely successful that they are to-day the largest manufacturers of carriages and harness in the world, selling to the consumer exclusively. They publish an extended illustrated catalog, which we will take pleasure in mailing to all our readers who request it, and mention the American Bee Journal when writing.

The Premium offered on page 172 is well worth working for. Look at it.

Selling Sections by Count is advocated by J. E. Crane, in the Bee-Keepers' Review. He thinks it absurd that the bee-keeper who produces thousands of sections of the same size and nearly the same weight should sell them by weight and then the purchaser should sell them by the piece. He thinks selling by count would have a tendency to the production of combs of more even weight.

Putting Empty Supers Over Partly-Filled Ones is practiced by many toward the close of the season, but is now recommended in the Progressive Bee-Keeper as a plan to be used all through the season for the sake of getting sections filled up more evenly in the super already partly filled. You may rely on the plan for getting the sections finished sooner, but there is also danger that the sections will not be so white.

Do Bees Get Used to Movements? is a question raised by J. H. Martin, in the Bee-Keepers' Review. He cites the common observation that bees are not so troublesome where they are visited daily, and if the movements of the people make the difference, why not movements of inanimate objects? He thinks of planting a dozen flags in his apiary, so that their continual motion may make the bees take less notice of the movements of the bee-keeper.

Boiling Foul=Broody Honey 15 Minutes is held to be long enough by the Bee-Keepers' Review critic. To the argument of Dr. Miller that Prof. McKenzie succeeded in getting spores to grow after being kept for 24 hours near 212 degrees, Mr. Taylor has a counter argument that will be hard for the Doctor to withstand. He says the specific gravity of honey is nearly a half greater than that of water, so its boiling point will be above 212 degrees, giving the spores a harder roasting in boiling honey than in boiling water.

Queen-Traps for Swarms.—W. Z. Hutchinson has tried leaving queens unclipped and allowing them to go with the swarms, till he is heartily sick of it. His preference is for queen-traps. He says in the Canadian Bee Journal:

"I have tried both the clipping of queens and the using of queen-traps, and my preference is for the latter. It saves the time and trouble of hunting up and clipping the queen, the time and trouble of hunting for and caging her when the swarm issues, and there is no danger of her being lost by the swarm coming out when no one is present to care for it."

One-Pound Sections Small Enough.—J. E. Crane says in Gleanings: "The fact that the many attempts which have been made to use a half or quarter pound section have ended in failure would indicate that a section less than 4½ x 4½ is unlikely to prove unprofitable and quite impracticable. I tried it myself some years ago, but have not cared to repeat the experiment. Bees seemed to dislike to build comb and store honey in very small receptacles, or else were unable, when clustered in very small bodies, to secrete wax, and build combs rapidly. We have learned by the use of single combs of various thicknesses the thickness of comb that bees can build to the best advantage, which seems to be somewhere from 1 to 1½ inches."

Quilt or No Quilt? In this country the tendency is toward discarding everything in the line of quilts and sheets, having nothing between top-bars and board-cover. Evidently the British colonies do not take kindly to this. The Australian Bee-Bulletin says it may do for comb honey but not for extracted. Disturbs bees too much in snapping up the board cover. The Canadian Bee Journal objects that too many bees are killed in putting on the cover. It may be a question worth considering whether in throwing aside quilts the bee-keeper may not be securing his own convenience at too great an expense in the way of comfort to the bees, but the man who is familiar with board covers without

quilts will feel inclined to smile at the objections as to taking off and putting on board covers. If it be admitted that there is no trouble in taking off such a cover from a super of comb honey, or from a hive upon which it is expected to put such a super, what possible difficulty can there be with an extracting-super? Are not bees just as plenty and just as irritable in one kind of super as the other? And it will be hard to convince one with experience in such things that he cannot put on a board cover without killing bees in a great deal less time than he can get on quilt and cover.

As to the Value of Queens.—"The Boiler in the American Bee Journal, 42, says 'In opposition to the views of Editor Hutchinson, who says queens are the least expensive part of a colony.... C. P. Dadant in Gleanings is emphatic in the assertion that in the spring the queens are the part of most especial value.' Why jumble language, brethren? Isn't the common air of 'most especial value,' and yet, isn't it the least expensive?"—Critic Taylor in the Bee-Keepers' Review.

That is a slight intimation that there is no difference after all in the views of the two men. Well, Mr. Taylor, look at the Review, 55, where Mr. Dadant says, "Queens, to us in early spring, are the most expensive part of a colony," and try your hand at reconciling that with Editor Hutchinson's statement that they are the *least* expensive part of a colony.

A Bee-and-Poultry Scheme is thus given by S. M. Keeler in the American Bee-Keeper:

"I have a small plot of ground that I sow to buckwheat the first of July, and seed it with crimson clover. The bees are ever ready for the nectar from both. When the buckwheat is ripe the hens are let in to harvest it, and grow fat. The clover comes in bloom the next spring, two or three weeks sooner than white clover, and just the time bees need looking to, to keep them from starving. And such a mass of red blossoms, and such a mass of bees humming over them, is very gratifying to the bee-man.

"Now, when the bees are done working the flowers, the clover is cut and cured, and run through a clover-cutter for the hens while they are in their winter quarters. Then the ground is put to buckwheat and clover again on the first of July. And so on every year."

Cold Facts in Favor of Plain Sections is what the editor of Gleanings calls the following statements (some would call them hot facts) by J. E. Crane:

"Will the evolution of the honey-box bring the plain section into general use? I believe it will. One dealer in Washington told me he would pay three cents per pound more for the 4x5 plain-section honey than for the old-style sections. Indeed, I was offered two cents per pound more, for 5,000 pounds of clover honey, to be delivered next fall, than I have been receiving of late for my best grade of honey, if put in plain 4x5 sections. In New York I inquired of Mr. Segelken for his plain-section honey, that I might compare it with that in old-style sections. He said he had very little left in plain sections, as such lots were picked up first by retail dealers, who preferred them to the old-style sections. I found the same true in Albany, N.Y., where I stooped to look over the honey. As these retail dealers are not in the supply business, I thought their opinions worth recording."

Ordering Supplies in Advance is very generally advised, and a sort of blame thrown on the man who does not send his orders some time before the goods are needed. By way of variety, a writer in British Bee Journal has this to say on the other side:

"I do feel, as a beginner, that this is a great grievance to us amateurs, who do not and cannot know, until experience teaches us, what we do want, and, in consequence, are kept waiting by tradesmen, who ought themselves to know by experience when, and to what extent, the rush of orders will come in. It is the only trade I know where the seller has the face to expect his customers to tell him beforehand what they will want: and in our case—I speak for us novices—we do not know, and the tradesman loses what might turn out afterwards to be good customers by the fearful delay in supplying the most simple and absolutely necessary articles, and thus frequently putting back a beginner to so late a date that he is unable to make a success by having everything *en train* at the proper time, and perhaps even disgusting him for good in consequence."

Root's Column

This is a **Queer World**. We cannot be made to see all things alike. Some like one thing, and some another. There is a class, no doubt, who hesitate to try Plain Sections because of the extra expense of the fixtures. There is another class who would not have them anyhow. Well, we are prepared to suit everybody. We have just brought out a slat separator to take the place of the ordinary tin or solid-wood separator.

They are simply four slats bound together at the ends by folded tins. They can be used in any super taking the old-style sections; and their cost is hardly any more than wood separators. We can supply them for 80 cents per 100, either for T supers or for section-holders. For odd-sized supers, of course we shall have to make additional charge. They can be supplied with our regular S super—that is, the supers with old-style sections and section-holders, or with our regular T supers.

Mr. J. E. Crane produced several thousand pounds of honey with separators of this kind, and he is of the opinion that the freer communication afforded gave him fuller and better boxes; but the boxes were hardly as complete and nice as those from fences.

Keep Your Eye on this Column, **as we may be able to save you dollars.**

The A. I. Root Company
MEDINA, OHIO.

GENERAL ITEMS

Report for 1898.

My report for 1898 is 42 colonies, spring count, increase to 85, and took 2,000 pounds of extracted and 500 pounds of comb honey, principally from cotton-bloom. Honey from this source granulates very readily on the first approach of cool weather. Our winter is now about over, and I have lost only 3 or 4 colonies.

Of course no man or woman should attempt to keep bees without a good journal, and also a text-book, and read and re-read the good items. Don't get them and lay them away.

J. A. ROSSON.
Ellis Co., Tex., Feb. 19.

Artificial Heat in Wintering.

I put 70 colonies into the cellar last fall, and they are all alive at the present time, but it has kept me guessing for the last month, for it has been from zero to 40 degrees below, and I had to keep a fire in my cellar most of the time to keep the bees in good shape. Don't tell me that artificial heat is bad for bees in this part of the State, for I have used it for three years, and have not lost a colony.

It was a poor season for bees last year, and I got only half a crop. From 50 colonies, spring count, I took 4,200 pounds of extracted honey, mostly white. I have kept bees 10 years, and do not know much about the business, but am learning every year. I give the credit to the American Bee Journal, "Bees and Honey," "A B C of Bee-Culture," and Doolittle's "Scientific Queen-Rearing," for every man ought to rear his own queens.

A. E. BRADFORD,
St. Croix Co., Wis., Feb. 20.

Good Season in 1898.

The season of 1898 was very good here, but the honey was all dark. I got about 400 pounds, but all was dark except about 50 pounds. I have 17 colonies, all doing well. I take great interest in bee-keeping, and like the Bee Journal very much.

S. M. HODGES,
Vermillion Co., Ill., Jan. 27.

A Little Bee-Experience.

The American Bee Journal has been a great help to me during the past year. I started by catching and hiving a swarm in the spring of 1897. They gave no increase or surplus that year. Last year I got no surplus from them, but they gave a swarm May 1, which I also hived in a box-bive. This new colony also gave a swarm Aug. 1, and 20 pounds of surplus comb honey. I also got one after-swarm from No. 1, which has built up; and I bought a swarm on a bush from another man June 21; this last gave me 40 pounds of nice section honey. The last three colonies are in dovetailed bives, and I want to transfer the two from box-hives in the spring.

E. L. HAYES,
Jefferson Co., Ill., Feb. 9.

Glorious Rain in Northern Calif.

We had a glorious rain last night. The weather is yet cloudy, and I believe we shall have occasional showers. The rain we had last night was very opportune; it will save the crops in the northern portion of the State, and somewhat in the southern central portion, where it has fallen. I do not think any rain fell in the southern portion of the State, at least this morning's papers do not mention such fact.

With rains every few weeks, and no drying winds, we shall have a fair crop of fruit, grain and honey all through northern California. I wish I could say as much for the lower part of the State. Those who have

BUGGIES AT WHOLESALE.

We manufacture a full line of Buggies, Phaetons, Surries, Spring Wagons and Road Wagons and sell them to you direct

From our Factory at Wholesale Prices.

This saves you all the extra expense of double shipment, traveling man's expense, middle men's profits, &c.

We make all the Vehicles we Advertise.

TWO WAGONS AT ONE PRICE.

It is a matter of great convenience and a saving of labor for a farmer to have a low, handy wagon. They save more than half the labor of loading in hauling manure, hay, grain, corn-fodder, wood, stones, etc. The man who already has a wagon may have one of these low handy wagons at the small additional cost for a set of wheels. These Electric Steel Wheels, with either direct or stagger spokes, with broad-faced tires, are made to fit any axle. You can convert your old wagon to a low, handy wagon in a few moments. You thus virtually have two wagons at one price. Write to the Electric Wheel Co., Box 16, Quincy, Illinois, for their catalogue, which fully explains about these and their Electric Handy Wagons, Electric Feed Cookers, etc.

It won't pay you to Buy from us

if you live in China, but if you live in Minnesota or Iowa, or even the Dakotas, you had better get our Catalog before buying. We keep a

been south tell me that things "are done for" there this year. 'Tis too bad. Hay is \$18 a ton here; I am told that south it is \$30. That makes it very hard on those who have stock, especially stock-raisers. Meat has about doubled; butter is higher than usual at this time of the year. Eggs are cheap enough; I learn that this State is shipping large quantities to the East. I suppose the warm weather here has caused hens to lay abundantly, while the very cold weather in the East has prevented the egg-crop from "maturing." **W. A. PRYAL.** Alameda Co., Calif., March 1.

A Rather Severe Winter.

Our 12 colonies gave us about 175 pounds of salable second-grade honey in 1898. We have had a rather severe winter thus far, and not having given them any better honey I expect some loss, but discouragement has not entered my mind.

D. H. HORST.

Holmes Co., Ohio, Feb. 28.

Bees in the Best Condition.

I started in the winter with 43 colonies, and haven't lost one to date. I find them in the best condition with plenty of bees and honey. I have kept bees for 20 years, and never had such "luck," as some people call it. I think plenty of young bees and good sealed honey, with dry hives, is the secret, tho the thermometer has registered 17 degrees below zero—the coldest winter I ever saw in this country. Success to the **Bee Journal.** **Geo. W. KNIGHT.** Oldham Co., Ky., Feb. 22.

Expect Heavy Winter Losses.

Bees did the next thing to nothing here last year. There was no surplus to speak of, and bees gathered but little to winter on. We have had three weeks of bitter cold weather, which will finish at least 90 percent of the bees that were out-doors. It would be impossible for them to get to their feed in such weather. Well, they might as well starve now as later on. That is what will happen to all the bees in this part before fruit blooms unless they are fed. Bees that are under ground will be all right until taken out, then they must be fed. I have now 20 colonies in the cellar, which are wintering nicely so far, but I will have to feed them in the spring. **L. C. WATTS.** Jasper Co., Iowa, Feb. 20.

Quite a Number of Dead Bees.

I hear of quite a number of dead bees through this county. Most of the new swarms have died, and some old ones, which were run for extracted, there being no fall flow, and nothing after basswood. **Linn Co., Iowa, Feb. 21. G. H. FREY.**

Good Report from Central California

All the bee-keepers in California are not quite so blue as Mr. McIntyre, of Ventura county, makes them out in the American Bee Journal of Jan 5. The bee-keepers in Southern California may feel blue, but I assure you they don't in Central California, where they get a crop of honey every year. It is not here like it is in the southern part of the State, where they only get a crop every fourth or fifth year.

I also saw that Mr. J. H. Martin (Ramblor) says the absence of moisture another season would about use up the industry in this State. It would be well for those gentlemen to state their location, and not compare their locations with the whole State. The counties of Kern, Kings, Tulare and Fresno are not to be compared with those barren rocks of Southern California. The counties above mentioned have thousands of acres of alfalfa for bees to work on, to say nothing about the thousands of acres of fruit-bloom, raisin vineyards and wild flowers in which the wastelands abound.

My crop for 1898 was 9½ tons of ex-

Doolittle's Book Free!

Every Bee-Keeper should have

SCIENTIFIC QUEEN-REARING.

YOU CERTAINLY will have it if you desire to know how to have queens fertilized in upper stories while the old queen is still laying below; how you may safely introduce any queen at any time of the year when bees can fly; all about the different races of bees; all about shipping

queens, queen-cages, candy for queen-cages, etc.; all about forming nuclei, multiplying or uniting bees, or weak colonies, etc.; or, in fact, **everything** about the queen-business which you may want to know. The price of the book is \$1.00, being bound in cloth, gold-lettered.

We want 1,000 New Subscribers

Between Now and June 1,

And we would like to have our regular subscribers help us in this work. In order that all who may want a copy of Doolittle's "SCIENTIFIC QUEEN-REARING" may earn it very easily, and at the same time aid in swelling the Bee Journal's list of subscribers, we wish to make the following **Liberal Offers**—only to our present subscribers:

Offer No. 1. We mail the book for \$1.00, or club it with the Bee Journal for one year—both for \$1.70.

Offer No. 2. Send us **Three New Subscribers** to the Bee Journal for the balance of the year, at **60 cents each**, and we will mail you a copy of the book free as a premium.

Offer No. 3. Or, send us **two** new subscribers to the Bee Journal for the balance of this year at **60 cents each**, and 40 cents additional making \$1.00 in all, and we will mail you the book.

Offer No. 4. Or, send us **one** new subscriber for the Bee Journal for the balance of this year at **60 cents**, and 65 cents additional making \$1.25 in all, and we will mail you the book.

Now, the sooner the new names are sent in the more copies of the Bee Journal they will get for their 60 cents, and if sent before April 1, each will be certain of getting the Bee Journal for **nine months**, or about 40 copies.

Remember, that only our present subscribers can take advantage of the last three offers above.

Now, let everybody go to work, and help roll up the 1,000 new subscribers.

Address,

GEORGE W. YORK & CO.

118 Mich. St., Chicago, Ill.

tracted, and 4½ tons of comb honey from 440 colonies; and lots of other bee-keepers did better than I did. And 1898 was not nearly so good as 1896, and a little better than 1897. R. H. FRAY.

Tulare Co., Calif., Feb. 5.

"California White Clover Honey!"

Some grocery stores in this city are selling extracted honey put up at Chicago in one-pound glass jars. It is all liquid with a small piece of comb honey floating in it, and is labeled "California White Clover Honey. Franklin McVeagh, Chicago." It is retailed at 10 cents per jar. Is there such a thing as California white clover honey? I had some curiosity to taste it, but did not like to buy any of it.

Jos. M. NIEMANN.

Jackson Co., Iowa, Feb. 18.

[Yes, Mr. Niemann, we got a sample of the same stuff you refer to, here in Chicago. It is a most villainous liquid. Of course it never saw California, but was put up by the firm named. What a pity that those who put up such vile stuff, and palm it off as honey, can't be put where they can't defraud honest people. It is simply a form of robbery, and often carried on by people that would feel terribly insulted if they were called common thieves, which they really are. All the difference between them and those that often are sent to the penitentiary is, that the former are often millionaires, and the others are poor fellows.—EDITOR.]

Bees in No. 1 Shape.

I presume all the readers of the Bee Journal will be glad that our little smoker apiary of 144 colonies showed up on Feb. 21 all right, with no more dead on the bottom-boards than usual, while the mercury was 10 degrees lower than for three years past.

My long, high entrances, all wide open, enabled me to clean the bottom-boards very handily of dead bees. Much has been written about wide entrances of late. All of my bees are treated alike, all having 7½-inch high by 12 inches wide, wide open, entrances. The hives have shrunk in weight since Nov. 10, an average of 11 pounds each, and now have 18 pounds all sealed honey, and no brood. They are dry, clean, and in No. 1 shape. T. F. BINGHAM.

Clare Co., Mich., Feb. 24.

Bees Seem in Good Condition.

I like the American Bee Journal very much indeed, and find much valuable information in its columns. Tho a subscriber for little more than a year, I feel I could not get along without it.

I have 130 colonies of bees wintering on the summer stands, and seemingly in good condition. Bees had a good flight to-day. I have this winter made 125 hives for use next summer, so you see I have not been idle. I have a nice 2½-story honey-house in which I can conveniently work in the winter. W. M. J. STEWART.

Utah Co., Utah, Feb. 18.

Something to Arrest Fermentation.

On page 82, Cogitator says that Mr. Hart wants salicylic acid to put in his sour honey. I do not think I do. It may be all right for some embalming purposes, or in some ointments, but, as Cogitator says, I should hardly think it healthy as a diet.

The honey was supposed to be ripe enough to work with, but aside from that feature it was all extracted within two days, and put up in Mason jars, pints and quarts. If unripeness is the matter, why would not all the honey be affected the same way? Whereas nearly all of it is nice, and only four or five quart jars show a little fermentation, but not bad.

The article I referred to said the recipe

given would arrest fermentation, and sweeten the honey, but did not say a word about any deleterious effects. We do not want to use it, only I thought it might do then to feed the bees this spring. Will it do? A. W. HART.

Stephenson Co., Ill.

Last Season's Results.

I started with 9 colonies in the spring of 1898, lost 2 by bad management, and had one fine swarm leave after I had hived it, but I had 9 colonies in good condition for winter. My average was about 30 pounds to the colony. I could not do without the American Bee Journal. DAVID J. OTT, Augusta Co., Va.

Only a Moderate Year (1898).

We very much appreciate the "Old Reliable"—could not do without it. We like the two departments, "Beedom Boiled Down" and Cogitator's "Afterthought." Last year was only a moderate one with us. From 260 colonies, spring count, we secured 20,000 pounds of comb and extracted honey, and increased to 325 colonies. We now have 450 colonies to commence with this year. We hope for a better year. O. P. HYDE & SON, Williamson Co., Tex., Feb. 16.

Starters in Brood-Frames.

I see a good deal said in regard to starters in brood-frames, and I wish to tell you the way I do. I make my frames with the top-bars one-half inch by one inch, then I take combs that are nearly straight and cut strips about half an inch wide, and glue them on the underside of the top-bar. It saves foundation, and is better. Warren Co., Pa. GEO. WHITCOMB.

A Beginner's Experience.

We had a poor season last year for honey. I purchast 21 colonies in box-hives and transferred them to frame hives. I got 300 fairly-filled sections, have plenty of stores for spring breeding, and lost but one colony by robber-bees during my absence from home for a few days. Isn't this doing well for a beginner? I had lots of trouble at first watering bees; they would get drowned in everything that held water. Finally I filled a pan level full with coarse gravel, and set it in the sun where water from a barrel would drip into it fast enough to keep it full. In a week I had all the bees in the neighborhood coming for water, and no more drowned bees.

Success to the American Bee Journal; it is worth dollars to me. W. H. BAKER, Yolo Co., Calif., Feb. 13.

Convention Notices.

Texas.—The Texas State Bee-Keepers' Association will hold their 21st annual convention at W. R. Graham & Son's, Greenville, Texas, the first Wednesday and Thursday in April, 1899. All interested are invited. No hotel bills to pay. W. H. WHITE, Sec.

Utah.—The Utah Bee-Keepers' Association will hold their regular semi-annual convention April 8, at 10 o'clock a.m., in the city and county building, Salt Lake City. A full program in the interest of the industry will be presented, and all bee-keepers are cordially invited. Among the subjects to be considered will be the purchasing of supplies, the disposal of our products, and the best method for the protection of the industry. It is desirable to have every county represented, either personally or by letter. Questions are solicited. Mill Creek, Utah. J. B. FAGO, Sec.

1Dtf

HONEY AND BEESWAX MARKET QUOTATIONS.

CHICAGO, March 7.—Fancy white comb brings 13c, and there is a good demand for it. No. 1 white is also wanted at 11 1/2c, depending upon quality. Lower grades of white, amber and mixt colors range from 8 1/2c, with dark and buckwheat 7 1/2c. Extracted white clover and sage, 8c; basswood and alfalfa, 7c; amber grades, 6c; buckwheat, 5 1/2c. Beeswax, 27 1/2c.

Market generally healthy in tone with best grades of honey scarce. R. A. BURNETT & Co.

DETROIT, March 9.—Fancy white comb—scarce and higher and we now quote it 13 1/2c; No. 1, 12 1/2c; fancy dark and amber, 10 1/2c. There is considerable poor honey in the commission houses which is offered at 8 1/2c. Extracted, white, 6 1/2c; dark, 5 1/2c. Beeswax, 25 1/2c. M. H. HENT.

KANSAS CITY, March 10.—Fancy white comb, 13c; No. 1, 12c; amber, 11c; dark, 10c. Extracted white, 6c; amber, 5c; dark, 4 1/2c. Beeswax, 25c. C. C. CLEMONS & Co.

NEW YORK, March 8.—Fancy white, 12c; No. 1 white, 10 1/2c; amber, 9c; buckwheat and dark, 6 1/2c. Comb honey is pretty well cleaned up now and we expect to dispose of the balance of our stock during this month. Excepting California there is not much stock of extracted on our market. Demand is fair at unchanged quotations. Beeswax, 27 1/2c. HILDRETH BROS. & SEGELKEN.

SAN FRANCISCO, March 9.—White comb, 9 1/2c; 10 1/2c; amber, 7 1/2c. Extracted, white, 7 1/2c; light amber, 6 1/2c. Beeswax, 24 1/2c.

Market is not favorable to buyers, more especially for desirable extracted, stocks of which are decidedly light. Comb is in moderate supply, and has to depend almost wholly on local custom for an outlet. Quotable rates remain as previously given.

BOSTON, March 10.—The demand for comb honey is very light, with full stock on hand. We quote our market: Fancy white, 13 1/2c; A No. 1, 12c; No. 1, 11 1/2c; light amber, 9 1/2c. No demand for buckwheat. Extracted, white Northern stock, 7 1/2c. Beeswax quiet at 27 1/2c. BLAKE, SCOTT & LEE.

OMAHA, March 13.—The stock of comb honey in this market is very light. There are not over 300 cases of all grades in first hands. Demand continues fairly active. Fancy white quotable at 13c; choice, 12c; No. 1 amber, 11c. Extracted well cleaned up. PEYCKE BROS.

BUFFALO, March 10.—There is only very little dark poor honey in our market, which is selling at mostly 8 cents. Some strictly fancy white comb honey would bring about 12 cents. Little, if any, here. No extracted to mention. Fancy pure beeswax, 30c. BATTERSON & Co.

CLEVELAND, March 9.—Fancy white, 13 1/2c; No. 1 white, 12 1/2c; A No. 1 amber, 10 1/2c; No. 2 amber, 9 1/2c; buckwheat, 8c. Extracted, white, 7c; amber, 6c; buckwheat, 5c. A. B. WILLIAMS & Co.

MILWAUKEE, March 2.—Fancy 1-4b, sections, 13 1/2c; A No. 1, 12 1/2c; No. 1, 11 1/2c; dark or amber or old, 7 1/2c. Extracted, in barrels or kegs, white, 7 1/2c; dark, 5 1/2c. Beeswax, 25 1/2c.

Since our last report we have had a very good market for honey, and the demand has been very good for all grades, especially for sections of the best quality, and the demand is good now and small supply. We encourage shipments of best comb. Extracted, fair demand. A. V. BISHOP & Co.

Eastern Bee-Keepers!

Why send West for your SUPPLIES, when you can get them near home, in less time, with less freight to pay, and at as low prices, quality considered. We keep in stock several carloads of

HIVES, SECTIONS, COMB-FOUNDATION, SMOKERS,

in fact, nearly everything a bee-keeper needs. We also have at Glen Cove, L.I., two apiaries, and sell from them

ITALIAN BEES AND QUEENS.

Untested Queens, after April 10, 70 cts.; 3 for \$1.80; Tested Queens, \$1.25 each. Colony of Italian Bees with a Tested Queen in a complete Hive, \$7.50. Catalog free. Fertile Eggs from heavy-laying White Wyandots, \$1.00 per 13; \$1.50 per 20.

I. J. STRINGHAM, 105 Park Place, New York, N. Y.

BEE-SUPPLIES!

We have the best equip. factory in the West. Capacity, one carload a day; and carry the largest stock and greatest variety of everything needed in the apiary, assuring our goods, at the lowest prices, and prompt shipment. **Illustrated Catalog, 72 pages, Free.**

We also manufacture Tanks of either wood or galvanized steel, all sizes, any form, for all purposes. Price list free.

Address, **E. KRETCHMER, RED OAK, IOWA.**

CONTRIBUTED ARTICLES

Several Opinions on the Origin of Honey-Dew.

MY attention has been drawn to an article on page 17, by my friend, Prof. Cook, on "Honey-Dew," and he sums up his article by saying that "Honey-dew is always a secretion from insects."

My object in writing is to say that I believe it is no longer a matter of conjecture, that under certain atmospheric conditions a saccharine substance or sweet juice exudes from the surface of the leaves of trees and plants. I at one time thought very much like Prof. Cook, but I have had ample opportunities of observing that in many cases insects have nothing whatever to do with producing honey-dew.

Some years ago, when I was staying at Hohwald, in the Vosges mountains, I had a very good opportunity of convincing myself that those were in the right, who held that plants do at times exude a sweet juice which is eagerly sought after by bees, while that produced in insect agency is very reluctantly taken by them, and then only when the natural exudation is not available.

Gaston Bonnier is one of the most careful observers and experimenters that we have at the present day, and he not only asserts that the leaves of trees do exude a saccharine substance under certain atmospheric conditions, but he has also been able to reproduce the phenomenon by placing the branches of trees in water and subjecting them to similar conditions. At any rate, he is not likely to be misled by not looking for the insects on the tops of the trees, as it is at the tips of the branches that any one but a tyro would naturally expect to find them. THOS. WM. COWAN.

Monterey Co., Calif., Feb. 20.

Prof. A. J. Cook, in his article on honey-dew, on page 17, hopes that all readers of the American Bee Journal will observe closely this honey-dew question and report.

Tho not a scientist, I have spent quite a little time in observing the origin of honey-dew, and from what I have seen and observed I have come to a different conclusion from what the Professor did when he says, "Honey-dew is always a secretion from insects."

I admit that much of the honey-dew is a secretion of insects, of which we can satisfy ourselves without climbing the trees where it exists, or where we find the honey-dew on the leaves by jarring the tree or brush, and looking towards the sun in the morning after sunrise, or in the evening a half or three-quarters of an hour before sunset, when you will see hundreds of sprays crossing each other in rainbow shape several feet high from where the insects stand on their legs while they operate their spraying-tubes. This is

quite a curiosity, as they will repeat their sprays a number of times, when the tree is jarred. The readers will see by this that the honey-dew will not only be found on the lower limbs and leaves of the tree, as the Professor indicates, but these sharp sprays will also reach the tops, as I have often witnessed on some plum-trees in my apiary, and on many other trees and plants.

But this does not prove that *all* honey-dew is secreted by insects, and that none exudes from plants and trees as a saccharine substance. I have seen my bees working lively on the joints of the cornstalks about the time when the tassels come into bloom; and when we had a dry spell previous to this, and then had a good, warm rain, which gave a vigorous growth to the corn, and an overplus of sap, probably more than the stalks could hold, and consequently produced honey-dew at the joints, there were no insects there. These conditions occur only once in three or four years.

C. Thielmann.

The honey is of very fine quality, and has a golden color. Some years I have received considerable surplus from this source.

Some years, when the right conditions meet, the birch-trees produce honey-dew in large quantities. Some years

ago I received from them about 1,500 pounds of surplus honey of the most delicious flavor, and almost water-white. The honey gathers at the junction of the leaves and the newly-growing twigs, where a small drop of "honey" can be seen from some distance away.

The birch and corn do not yield honey on their blossoms any more than does hazelbrush, at least I never saw bees work at all on the birch-bloom, but I have often seen them work on corn-tassels for pollen. Some bee-keepers claim that bees do not gather honey from corn-blossoms, which I think is correct.

The honey-dew on the birch-trees does not fall on the leaves like a "gentle rain," but drops on the leaves below from where it exudes, if not taken up by the bees or other insects. I have seen the honey glistening at the junctions of the birch twigs, only a few rods from my apiary, while the bees were briskly gathering the nectar. My bees sometimes were in such excitement that you would think every colony was swarming; but as soon as the condition of the atmosphere changed the excitement ceased. Sometimes it lasts only a day or two, while four or five days is the longest I have seen it in one season.

I am positive that this is no insect production, for I have examined it very closely and persistently.

I am not so sure that the acorn honey is an exudation of the overplus of saccharine substances of the tree or the acorn, or whether the acorns are pierced by insects to make the sap or nectar flow from them; the Professor seems to be "on the rail" himself about *this*, and seems to be anxious to know if the acorn honey-dew always comes from what he supposes to be wounds of the nuts by insects. (See page 459 of the American Bee Journal for 1886.)

I have examined the acorns closely from the lower part of a tree to the very top, but have not discovered any larvae nor any caterpillars on them, nor any other insects; but nearly all the acorns on the same trees were wounded horizontally right above the acorn-cup from which the "tannin" nectar oozed. The wounds extended to the center of the nuts, but I did not discover any larvae, tho I examined only some of them closely. I will make a more extended search the next time I get a chance.

The acorn honey is the poorest in taste and color of anything my bees gather.

In conclusion, I find that honey-dew is not "always" a secretion of insects, and that some trees and plants produce nectar under certain atmospheric conditions, regardless of insects, or blossoms, and that the definition in our dictionaries is in line with my experience.

Wabasha Co., Minn.

C. THELMANN.

I have read the article on page 17, from Prof. A. J. Cook, in regard to the origin of honey-dew, and as he invites the readers of the American Bee Journal to make close observation and report our experience, I will report.

I am 60 years of age, and have handled bees more or less all my life, and now have 72 colonies. I have seen honey-dew as far back as I can recollect; I used to lick it off the hickory leaves when a child, because it was sweet. I have seen it on trees, shrubs, and all kinds of grass, and I have found it on my oilcloth when I was a soldier. I have found it on the plains, and much of what I know has been learned from observation. I have given it a great deal of thought, and my observation has led me to the conclusion that there are two kinds of honey-dew—one is the exudation of insects, and the other is caused by the conditions of the atmosphere, and falls as dew from the heavens. So thoroly am I convinced of this that I am astonished that a man so well informed as Prof. Cook should not know that there are two substances called "honey-dew."

The exudation of insects is a filthy sweet, not fit for man or bees, and when there is plenty of it, and no genuine honey-dew, the bees will deposit a lot of this worthless stuff; but if there is a good fall of honey-dew, the bees will leave this bug-juice and gather what is called a good honey-flow. This genuine honey-dew is clear as crystal; I have seen it hang in great drops on the blades of grass. We used to get our best clothes spoiled with it when we went thru the grass to Sunday-school when we were children. I have also seen it on the bunch-grass on the plains, and I have seen the cattle that run at large on the prairies with their horns all gummed and daubed over with honey-dew in great profusion where there were no trees to climb, and no aphids to be found—nothing in all the scope for them to subsist on.

This honey-dew makes the best of honey. A test will prove that it will candy quicker, and be whiter than the exudation of insects. Atmospheric conditions may occur when there is an abundance of insect exudation, and the

two may be mixt. But at the same time the genuine honey-dew may be found where no aphids or honey-exuding insects exist. The exudings of insects are odorous, while the genuine honey-dew is not, unless perfumed from the fragrance of flowers. It is the condition of the atmosphere that causes nectar to secrete in flowers; the same conditions cause honey-dew to fall.

Volumes may be written on the best kinds of honey-plants, but all fail to secrete nectar unless the proper conditions of the atmosphere are at hand. How often do we hear complaints that there was no nectar secreted in the white clover, or in the basswood bloom; and I have even read of sweet clover failing to secrete nectar. The flowers of all honey-producing plants are susceptible of secreting nectar when the conditions are present. Some are more susceptible than others. Thus we have our best honey-flow one season from one flower, and sometimes from another flower, owing to the congenial conditions for the one flower or for the other.

We must look above the trees for our blessings. Is it not just as reasonable that honey-dew is a result of the conditions of atmosphere, as it is for the elements to be full of malaria or of some epidemic? S. W. MAXEV.

Kittitas Co., Wash.

I have heard and read a good deal about honey-dew lately, so thinks I, I'll keep mum, those other fellows having said enough concerning it. But after reading Mr. Nash's article, on page 98, and tussling and gurgling it for awhile, it failed to go down. He thinks Prof. Cook is wrong about his statement, that honey-dew is deposited by insects or bee-lice, as we call them here.

Again, he says some facetious writer calls it "bug-juice." 'Tis naught else but bug-juice, pure and simple. I have had experience with it some six or seven years, and have never failed to see the little fellow that makes the juice. But 1898 capt the climax. In the spring we get a few sections of it from extra-strong colonies, but last year I received between five or six hundred sections filled with honey-dew. Some people even go so far as to think, or say, that this filthy stuff comes from heaven. Had the promist land flowed with milk and this kind of honey, our forefathers would have gone to the "Himmels" pretty quick.

These insects, or tree-lice, are mostly found in spring on the plum-trees after fruit is set, and, if not taken care of very soon, will ruin both tree and fruit. They are almost always on the underside of the leaves. (That is the reason why this honey is always on the upperside of the leaves and not on the underside.) I have seen them so numerous as to cover both branches and leaves completely from stem to stem, and if disturbed would give you a small shower-bath. But last year they were just as numerous on both the hickory and black oak. The underside of the leaves would be covered with small lumps, resembling warts, and on being broken open would contain a small larva of these insects, which lie dormant until warm weather of spring hatches them.

Another peculiarity about honey-dew is this: Bees will not work much on anything else when they can get this stuff. We had about as much sweet clover in 1898 as the season before, but nary a bit of sweet clover honey did we get. Bees that have not been fed in the fall, or those wintered in small hives without protection, have surely "gone up," as the cold has been very severe here, bees not having a flight in six weeks.

I do not want to cross swords with Mr. Nash concerning his article. Maybe trees do sometimes have a "sweating spell," but I have failed to see them in such a sweat without having good reasons to do so.

Cook Co., Ill.

PETER J. SCHATZ.

Rendering Beeswax—How Loss May be Avoided.

BY I. W. BECKWITH.

WHEN the comb is new, and especially when it contains honey, and the weather is hot, there is probably no better method of rendering it into wax than by the use of the solar extractor; but with the conditions reversed, the solar is "no good." In my experience with old, black comb I get little or no wax in this way; it being nearly all left in the residue, which, on getting cold, is as solid and hard as a lump of wax. One writer, I think it is Dr. J. P. H. Brown, of Georgia, says he thinks it is no loss to have this wax left in the refuse, because it makes such good fuel. It seems to me that wax at 25 cents a pound is rather expensive fuel; besides, the waste will burn just as

well without the wax; and as that from the solar extractor is nearly half wax, I propose to tell how to save it.

For a press I take two pieces of 2-inch plank 10 inches wide, and 3 feet or more in length, and cut them into the shape shown in the accompanying engraving. In the lower plank, near the wide end, I make a hole 2x3 inches in size, and across it string 6 or 8 wires, fastening them with nails or staples. Now lay one plank on the other, with some sticks between to hold them about $\frac{1}{4}$ of an inch apart, and hinge them together with a pair of 6-inch strap hinges, bending the hinges to fit. Tack a 6-inch piece of cloth around the wide end of the upper piece, letting it extend up as far as the narrow portion. This is to catch the wax that otherwise might fly out and soil clothing, furniture, etc. This cloth is not shown in the picture, as it interfered with a clear view of the press.

Get a tub—one 10 inches deep cut from the end of a barrel will answer—fasten a bar across it 3 inches from the top and 6 inches from one side. Put the lower end of the press on this bar, and the other end on some object that will raise

Rendering Beeswax.

it off the edge of the tub. Throw the upper handle back against the wall or some other object. Soak the tub, and have a little water in it. Warm the press just before using by pouring hot water on the inside faces. Make a strainer-holder of a piece of No. 6 wire fastened to the tub, so that the top-ends will be about 6 inches apart and 8 inches above the top of the tub. Make a sack-strainer 9 inches wide and 16 inches deep of some strong stuff—I use a piece of seamless grain-sack.

The method of operation is as follows: Put a boiler containing a pail of water on the kitchen stove; and when it boils make the fire as hot as you well can; then stir in comb as fast as it will melt, but not much faster, continuing to do this for about 15 minutes. Let it stand, stirring often, and when it boils freely set it by the side of the tub next to the strainer-holder. Hang the strainer on the holder, hold it open with the left hand, and fill $\frac{1}{4}$ to $\frac{1}{2}$ full. The more liquid wax it contains the greater the quantity that can be put in. There is not much gained, however, by putting in a large quantity, while it increases the danger of bursting the sack. Lay the strainer on the press with the bottom end next to the hinges, fold the top end back on the filled part, then bring down the handle and put your weight on it if you are not very heavy. As soon as the wax is nearly done running, dip your fingers in cold water, throw back the handle, lift the edge of the strainer which is toward you, fold it back on itself, and bring down the handle again. Throw back again, turn the strainer one-fourth round, fold back and press again; each time making the fold as even in the center as you can. You will now have a "cheese" about 4 or 5 inches square, perhaps an inch thick, and in four equal layers.

If you have done your work well you will now have no wax in the residue; which will shake out almost like dry

meal; while the strainer will be entirely free from wax except at the edges. If you have *cooked it too long* the cocoons will have become so viscid that when you bring pressure to bear they will stick to the strainer like a mass of glue, and you can get nothing from it. I think the greatest reason why rendering wax by boiling is not more popular is that it is generally *cooked too long*; so, keep the fire hot, and cook only a short time. If the contents of the boiler are likely to become too cold while you are straining, put it back on the stove while you press; but you should not be more than two minutes filling and pressing a strainer full.

Don't put the hinges too near the corners, since the pressure is mostly near the middle, or you will be liable to split the plank.

Don't put much heavy comb in the boiler at one time, and leave it without stirring, or it will be liable to burn and so color the wax.

Don't put any lumps of wax in the boiler after any comb is in; as the lump will be so long melting that the cocoons will be liable to cook too long.

Save all the residuum from the solar extractor, and, at the end of the season, chop it very fine, boil it, and then run it thru the press. The blackest comb will make almost as light-colored wax as will the lightest combs, if it is not cooked too long.

Dr. Miller, in reply to the question, "How can I keep the wax from sticking to a wooden mold?" replied, "Wet the mold." I will inform the Doctor that no amount of wetting or soaking will keep the wax from sticking if the wax is put into the mold very hot, and then cooled slowly; as the hot wax will drive all the moisture from the surface of the wood, leaving it dry, and then the wax will stick.

The Doctor has also told us to cool the caking wax in any vessel very slowly to prevent its cracking near the edges. When convenient I set the vessel of caking wax into ice-water, and if it shows a tendency to crack, as it seldom does, I run a thin knifeblade between the wax and the tin, cutting no deeper than $\frac{1}{2}$ inch, and have no more trouble.—Bee-Keepers' Review. Fremont Co., Wyo.

An Experiment in Producing Extracted Honey.

BY C. DAVENPORT.

AS most of the readers of the American Bee Journal probably know, I make a speciality of comb honey, but I have the last few years run a number of colonies for extracted, and perhaps the results of another experiment in this line which was conducted last season may be of interest to some.

Early in the spring, 30 colonies in good condition, all in 8-frame hives, were selected. They were divided into three lots of 10 each. In lot No. 1 the queens were confined by zinc to the lower story; in lot No. 2 they were allowed two stories for brood-rearing; while lot No. 3 had no restriction in the way of zinc, the queens being allowed their will in three or four stories. Perhaps I should say that with all, the upper stories were of full depth, and were placed on top instead of under the brood-nest, care being taken to give these upper stories as fast as they could be occupied, so that in lot No. 3 the queens had unlimited room for brood-rearing thru the entire season; and while lots Nos. 1 and 2 were confined to one and two stories for brood-rearing, they had all the drawn combs they required for storage.

The flow from miscellaneous sources in the spring was sufficient to keep up brood-rearing, and the weather on the whole was more favorable than the average of springs here. I do not remember ever having colonies in better condition in the spring than they were last season.

The flow from clover opened and continued in a scant, irregular way for about two weeks, when basswood commenced to yield. This basswood flow was at no time very profuse, and clover and basswood were both worked at the same time—something that seldom occurs here, for usually when basswood commences to yield everything else is largely forsaken for it.

An interesting thing to note about basswood is its different characteristics in different localities of about the same latitude. Mr. Doolittle says in his locality he never knew it to fail to yield considerable honey, while last year was the first basswood honey here, so far as surplus was concerned, for three years; and it not only fails to blossom here, but I have seen the trees literally loaded with bloom when it would fail to yield, and while there have been many theories advanced to account for this, I believe there is some reason or cause as yet unknown, for I have known it to

yield well some years, where in others, with apparently the same climatic and atmospheric conditions, it would be an entire failure. But while basswood often fails, it may be of interest to state that there was never a failure from all sources known in this section. The late Mr. B. Taylor, who was engaged in bee-keeping in the southern part of this State for over 25 years, reported, I believe, that about 50 pounds per colony was the smallest crop of comb honey he ever had. I have not done as well as this myself, but I have never failed to get each season from some source what might be called a paying crop.

An incident somewhat curious in this connection occurred a few years ago. That season, if I remember rightly, the yield from both clover and basswood was light, but later a large amount of light surplus honey was secured from a species of sunflower. This plant was described and illustrated some time ago in *Gleanings* in connection with a description of a visit the editor made to Wisconsin.

The season I have mentioned, this plant blossomed here in great profusion, and seemed to yield nearly equal to basswood, but altho it blooms here more or less each season, I never knew it to yield much in the way of surplus before or since.

Of the 10 colonies which composed lot No. 1, and in which the queens were confined to one story, 7 swarmed; of the 10 comprising lot No. 2, in which the queens were allowed two stories, 6 swarmed; and in lot No. 3, where the queens had unlimited room, there was no swarming. Nothing to prevent swarming was done with any of them, except in the way of ventilation and shade, and all were treated about equally in this respect.

From lot No. 1 about 500 pounds of white clover and basswood honey was extracted. About the time of the last extracting the indications were that there would be no fall honey, so in order to avoid feeding, if this was the case, as it turned out to be, enough honey was left in the frames of each colony in all three lots to carry them over to the following spring.

From lot No. 2 about 175 pounds was obtained. Those in lot No. 3 were only able to spare about 150 pounds, all told. No increase was allowed, for the working-force of all colonies that swarmed was kept together, and the two finally merged into one again; and in lots Nos. 1 and 2, in which swarming occurred, there was a small amount in the way of wax to be added in their favor; aside from this it will be noticed that the colonies that had their queens confined to one story yielded considerable over three times as much surplus per colony as did those whose queens had unlimited room. The matter is explained by the fact that eight frames were about all the queens, on an average, could keep full of brood and eggs in time for them to develop into field-bees for the main-flow. Later an immense force of bees was reared by those colonies that had more room, and these thousands of extra bees per colony were reared from, and had mostly to live upon, what the lesser force were able to gather during the flow.

Here I would like to say that I have never said, or at least never intended what I have written to mean, as some have since claimed, that the average of queens could not keep more than eight frames filled. What I did say, or intend, was *at the right time*; and by this I mean so that the brood and eggs will develop into bees that will be of service in securing the main harvest. A force of bees reared out of season to be of value as field-bees, in excess of what is required for the welfare of the colony, are a large factor in reducing the amount of surplus; and in my opinion this matter is not given the consideration its great importance should insure it. But it is no more than fair for me to say that it is very seldom that the conditions of a season here would be as favorable to, and allow, such an immense advantage to be shown in favor of a single brood story, for we had a great drouth here the latter part of the season, and nothing much was secured after basswood. While it is no uncommon thing not to get any surplus fall honey, I never before remember when at least some was not stored in the brood-nests, and if this had been the case last season more white honey could have been taken from lots Nos. 2 and 3.

Another thing that perhaps I should say is, that on account of the colonies comprising these two lots being stronger in bees, I considered it necessary to leave, on an average, probably seven pounds more per colony than in lot No. 1.

In giving the different amounts of surplus from each lot, I have said "about" instead of giving the exact amount. This is for the reason that it was measured in-

stead of being weighed; but the amounts would vary but a few pounds either way from the figures given.

Before closing, it may be better to mention for the benefit of beginners, that it would not have been a difficult matter to handle the swarms from lots Nos. 1 and 2 in such a way that the results would have been as much in favor of lot No. 3 as it is against it. As I have said, with the colonies that swarmed, the entire working force was kept together. If they had been allowed to divide up and increase, the results would of course have been altogether different. While this swarming made extra work with two lots in which it occurred, it was but little more than that of handling and looking for surplus honey in two or three stories containing more or less brood, and the other work that this entailed. I would like to explain just how those swarms were treated, but the space I am allowed forbids.

Southern Minnesota.

The Spring Management of Bees, Etc.

BY C. P. DADANT.

[Continued from page 165.]

In the previous article I called the attention of the reader to the necessity of great caution in feeding. It is worthy of notice that the excitement, which I have mentioned, does not continue as intense if feeding is practiced regularly with certain colonies. The bee is a very sagacious insect, and very soon discovers in what manner the food comes. Fed for a few days in succession in a certain spot, a colony of bees will thereafter expect the food in the same manner, at the same hour, and in the same spot. The excitement diminishes and the danger likewise.

Now as to the effect: Bees fed with combs of sealed honey will use this honey sparingly, just as if it had been their own crop. But when fed with liquid food, especially warm food, the effect is the same as that of a honey crop. It entices them to breed. Each bee, as it carries its load from the feeder to the cell, seems to impart the news to all it meets. The honey-sacs are all more or less loaded with the welcome sweet, and the queen is offered more food than otherwise. So her laying propensity is increased just as much, and in the same way, as that of the barnyard hen when the winter's manure is thawing out.

If too much food is given, the bees will store it in the cells, and fill them up unduly. So this also must be guarded against. We are feeding only for breeding, and must leave the room for brood. All we need is to make the bees feel that they have a sufficient supply to encourage them to continue their breeding. If the hive is well sheltered, and the space is adequate to the present needs, there is no need of fear of chilled brood.

The feed given must not be as thick as the winter food, and if honey is used it is advisable to add a small quantity of water. We all know that the bees need more water when feeding brood on old honey than on fresh nectar; and I believe that thin food, if not unreasonably thin, will induce more rapid breeding and require less trips for water. The water-hunting, in my opinion, is responsible for more spring losses than any other item, unless it be actual want of food.

As our colony grows and becomes more populous, the queen will enlarge her circle and more combs will have to be added to the room of each weak colony. Here, again, discernment must be used. If too many combs are given at one time, and if some of them are placed between the brood-combs, some risk may be run of chilling the brood. This is the most dangerous practice, and I believe more objections have been raised against the spring forcing of bees from this practice than from any other. Yet, if the weather is good, and the thing is not overdone, I know that something may be gained by placing empty combs between combs of brood. The outside combs usually contain pollen and honey, and act as a partition-wall when dry combs are placed beyond. If the queen goes to these empty combs, her brood is practically divided in two, and she will often be compelled to delay her laying in those combs, owing to this objection. But if the last comb of honey and pollen is drawn outward, and the empty comb placed between two combs of brood, she will readily fill it with eggs. The apiarist is thus called upon to judge, by the strength of the colony, the number of bees, and the age of the brood, whether he may safely increase the space.

If things are carefully done and a vigilant eye kept over the hives, this method is by far the most successful. The populous hives themselves may be made much more service-

able to the apiarist with a little timely feeding. Some of my readers may have occasionally noticed in the spring a colony or two in any apiary running over with bees, and fairly roaring with activity while the others are only slowly progressing. A close watch would have shown you that these two or three colonies have had a little extra feed in the shape of stores from deceased colonies whose condition had not been perceived in time to prevent the strong ones from robbing the little honey remaining in their combs. If such accidental feeding is productive of so wonderful results, what may not be achieved by judicious provision?

But in spring management, such as I have described, I repeat it, much discernment must be used. It is only the careful man who will succeed by constancy and perseverance; but his success will be gratifying when he compares his results with those of his more careless neighbor.

As to question No. 2, in Mr. Gray's inquiry, I would advise to use the full combs on which to hive swarms, and the foundation for the extracting-story, if a choice is to be made. In hiving a swarm on sheets of foundation there is always more or less danger of its being pulled down by the weight of the bees, before it is fairly fastened at the top; while in producing honey the bees gradually occupy the combs and have ample time to fasten the edges to the wood before loading them with honey.

For extracting-supers we use combs only six inches in depth, and have never had any trouble in using foundation for this purpose. We would not alternate built combs with foundation except where an additional brood-comb is accidentally required, because it usually happens that the bees lengthen out the combs while also building the foundation, and the one becomes out of proportion in thickness to the other.

Hancock Co., Ill.

CONVENTION PROCEEDINGS

Report of the Chicago Bee-Keepers' Convention.

BY A SHORTHAND REPORTER.

[Continued from page 163.]

The question-box was then taken up by Dr. Miller, as follows:

WAX-SCALES IN FRONT OF A HIVE.

QUES.—I have noticed a considerable quantity of wax-scales, like sawdust, before each hive—what is the reason for it, and of what import?

Dr. Miller—I remember very distinctly the time when I went off some little distance to ask that question of a neighbor; I was somewhat exercised over it. One thing you will notice, if the bees have not been disturbed, you will find it in streaks along under the frames in rows. In Germany they take that, carefully sift it, melt it up and get what wax they can; we don't do it in this country; the Germans are much more careful about saving anything than we; it is simply cappings and remains that are thrown down by the bees.

HANDLING BEES ON A HOUSE-ROOF—FOUL BROOD.

QUES.—What is the best method of handling bees in a city on the roof of a house? What number of colonies would be the most profitable?

Dr. Miller C. F. Muth, who unfortunately committed suicide not long ago, possibly had more experience in that line than any other man in the country. I don't know that the handling of bees in his case was any different from what it would have been on the ground. There are some things that make a difference, for instance, the swarms—and I would like to know more particularly what the questioner had in mind. When an apiary is kept on the house-top, for instance in the city as Mr. Muth's was, it would not be so convenient for him to have them swarm, and perhaps a little different practice would be used in that respect. Let me see, how many are there here who have had experience with bees on housetops? I don't see any hands. I should certainly have all queens' wings clipped. I should take the same course as with the bees on the ground.

Hundreds of colonies might be kept in one apiary in some places; and perhaps it might not be profitable to keep more than a small number for lack of pasturage in some places and some States. Chicago is one of the best cities,

where its suburbs give so much sweet clover, and perhaps a hundred colonies might be kept. I don't believe you would feel very safe in going over that. Perhaps not over 75.

QUES.—Are bees in any particular climate affected by foul brood more than another?

Dr. Miller—So far as I know foul brood will work in any climate, and it is not a new thing by any means, altho with a great number of bee-keepers perhaps it is a new topic and a new subject, yet there is nothing very new about it. It has existed for many years, and I don't know when the disease came; I know that more than a hundred years ago it was well known.

BEE-KEEPING IN TOWNS AND VILLAGES.

QUES.—Is it advisable to encourage bee-keeping in towns and villages?

Dr. Miller—What is bee-keeping for? Two things—getting the honey, that is one thing; that is not the main thing. The main intention, I suppose, for which God created bees, was to have them fertilize the flowers, and wherever there are flowers of a kind that need fertilizing by bees, there it is a good thing to have bees kept. They are in towns, and about towns as well. I should say it is a good thing to encourage the keeping of bees in towns and cities, everywhere; from a selfish standpoint I should say, "No, I don't want everybody to keep bees; I want to have a monopoly of the honey-trade." But when you come right down to it, the greatest good for the greatest number, bees should be scattered all over the country wherever flowers are, to fertilize them, and this includes towns and villages. It is the same in villages and towns, precisely the same as it is everywhere else; it is desirable for the sake of the fertilization of the flowers to have enough bees everywhere to do that work; it is also desirable to have everywhere enough bees to secure nectar that would otherwise go to waste. Now, there you have the whole thing; there is that nectar that would go to waste if there were not enough bees to gather it, so it is desirable to have enough bees to get it.

HOW MANY COLONIES IN ONE APIARY?

QUES.—How many colonies can profitably be kept in one apiary in a city or town?

Dr. Miller—Just the same as elsewhere. You can tell something about it, but it's hard to know for certain; every now and then some one will say that there can be three or four hundred kept in a place. I remember a gentleman a few years ago; I was very much interested in watching him; he said he was going to keep so many colonies, naming about twice as many as I felt safe in keeping, but he was unsuccessful. It is like anything else, you must go according to your pasturage. One man in California has kept 600 colonies in one place; it is possible he might do better with 500; it is one of the things you don't know about. I might have 100 colonies and not get as much honey as if I had only 80 or 90. The next year it may be a better season, and 110 will do just as well as 100; you see how it is; if you live a thousand years you will know more about it than you do now; it is very difficult to tell in a city or town; it may be that it is just exactly the same thing in the country; it may be a little different; it depends upon the pasturage. If there is any one that has any definite knowledge about this, we would be very glad to hear. Mr. Kreutzinger, can you tell us how many colonies can be kept in one place?

Mr. Kreutzinger It depends; I have had 114 in one place; 84 have done better. I find that around Chicago (Cook county especially) there is plenty of sweet clover—100 colonies can be kept in one place safely; other places where there is only white clover which is to be depended upon every year, I would rather recommend 80 colonies, no more; in other places where basswood is you can have a thousand colonies in one place.

IS COOK COUNTY OVERSTOCKT?

QUES.—Is Cook county, Illinois, overcrowded with bee-keepers?

Dr. Miller That is not a question for me to answer; I don't know how many bee-keepers there are in Cook county; it will bear a very large number of bee-keepers.

Mr. Moore—There are about 150 persons keeping bees in Cook county.

Dr. Miller—If there are as many as 200 there are probably as many as the ground will stand; a man can't keep a very large number of bees; if he cares for the money return he becomes a little discouraged if he can't increase and have a larger number. I should think Cook county differs very much from other counties, because there being so much larger population there is a larger number of people who will be interested in bee-keeping and entirely inde-

pendent of the money return in it; you will find amongst so large a number of people as are in Cook county, here and there a man who cares so much for the thing that he would keep perhaps a half dozen colonies to study, even if he had to pay for the privilege of keeping them and give away the honey besides. Perhaps I am inferring there is a little too much enthusiasm on the subject. In my own case, altho I have kept bees for more than a third of a century, if it cost me something to keep them I would not be without a few colonies on account of the interest I have in bees. You will never find the time to come when there are not some new questions and problems to study over; at least it has not been so up to 1898; I don't know what 1900 will bring. I should say that Cook county is not overdone with bee-keepers. I think likely there is some danger of the ground being over-stocked with bees if there are 200 bee-keepers, or even 150, and each one should keep a considerable number of bees; there is some danger in that direction.

PROTECTION AGAINST OVERSTOCKING WITH BEES.

QUES.—What protection can a bee-keeper get against another bee-keeper coming into a locality already overstocked with bees? In my neighborhood we are well stocked. Last spring a Chicago bee-keeper moved several colonies of bees within a few blocks of my apiary, which were neglected so much during swarming-time that small clusters could be found on bushes and under sidewalks. Do you think such careless management will cause the public to get laws prohibiting bee-keepers from keeping bees within the city limits? Within a circle of 1½ miles from my apiary I have located 172 colonies of bees. What protection can a bee-keeper get when overstocked with bees?

Dr. Miller—So far as I know there is positively no protection he can get at all from existing laws. There is a moral protection he may have if his neighbor is an intelligent person. If the locality is already overstocked an intelligent bee-keeper would hardly want to go into that locality for two reasons: In the first place, on account of his selfish interests, and, in the second, out of respect for those who already occupy the ground. There is first and last a good deal said about intruding upon territory already occupied, and there is a moral side to the question, so that it is generally considered that a man, if he is well informed and of good principles, will not want to go into a locality already fully occupied. It is damaging to him and to those already on the ground. A wise man will desire to find a field unoccupied; however, things of this kind will sometimes occur, and I don't know of anything that will help the case except to try to talk to a man and inform him.

A Member—I would suggest an injunction.

Dr. Miller—That won't count; can't do it. If you have the place, and have say 100 colonies of bees, and that 100 colonies fully occupies the field, and I can buy or rent a lot of ground within 10 rods of you, I can put my bees down there and you can't help yourself.

Mr. Moore—By the way, Dr. Miller, I had a notion to break in at the start and ask if this is not a sore spot. There has been some pretty lively discussion between yourself and others, and the editor of *Gleanings*.

Dr. Miller No; *Gleanings'* editor has been almost always on my side.

Mr. Moore You took the ground that a man had a sort of a vested right if he got there first.

Dr. Miller All agree on that. If you have the ground already occupied it is a mean thing for me to come in and "fish in your hole," as the fisherman says; that is the way it stands; all agree on that. I believe the time might come when it would be a desirable thing if in some way I could secure a certain territory where I know that no one will come in and intrude upon me.

Mr. Moore Some one has asked the question, "Does a man when he deeds 600 acres of land deed the bee-pasturage?" It was answered that he deeds the land, and he does not give any title whatever to the nectar in the flowers, but the time will come when he can buy the nectar on 600 acres by paying for it.

Dr. Miller I am afraid I said that; nobody in this world would be foolish enough to say that but me. Prof. Cook once said, "This much is certain, that you can't hold the nectar; it belongs to the public."

Dr. Miller Another question is involved: Do you think such careless management will cause the public to get laws prohibiting bee-keepers from keeping bees within city limits? Certainly, bee-keepers should not keep bees where they may disturb others. We should be exceedingly careful. While I may have the legal right to keep my bees within so short a distance of another man's house that they

will make trouble for him I have not the moral right, and I am very foolish if I do it. It is a great deal easier to *keep* out of trouble than to *get* out of trouble. You should be exceedingly careful not to do anything in that line that will make trouble for others.

DISTANCE TO KEEP BEES FROM HIGHWAY.

QUES.—Would a law governing distance from public highways to which bees could be kept be beneficial to bee-keepers?

Dr. Miller—I somewhat doubt that. They have some laws in the old country with regard to it. It is possible that it would be in some cases a good thing, but there is so much good common-sense in this country I very much doubt whether a law of that kind is needed.

BEST HIVE FOR WINTERING OUT-DOORS.

QUES.—What is the best hive to winter out-of-doors in Cook county?

Dr. Miller—I don't know, and if you commence talking about that you will spend all of your time. Here is a man who is certain that his hive is the very best in the world; and another who knows his is worth three of the other man's, and so on. If you have had success with a hive, that is the hive for you, and it is quite possible that what you have done the best with may not be the best hive for me to winter bees out-doors.

WINTERING OUT-DOORS OR IN THE CELLAR.

QUES.—How many Cook county bee-keepers winter their bees out-doors?

Dr. Miller—How many winter their bees out-doors? [16.]

Mr. Kreutzinger—I am keeping my bees in a shed specially constructed. I used to keep them in the cellar, but somehow water got in.

Dr. Miller—I would like to hear from some of the rest who don't keep their bees out-doors, and don't keep them in the cellar?

Mr. Doerr—I winter my bees in a specially-constructed bee-house, made of one-inch lumber.

Dr. Miller—I suppose that would be counted out-doors? How many keep your bees out-doors all the year around, thru the winter just the same as in summer? [2.] Tell us about how many you winter, Mr. Goelet.

Mr. Goelet—23.

Dr. Miller—How many thru the season?

Mr. Goelet—21.

Dr. Miller—Will you tell us whether there is anything to protect them particularly from the winds all the year around?

Mr. Goelet I have them fairly well guarded from the north wind, alongside a big fence. I have double hives packed with sawdust.

Dr. Miller—You keep them packed winter and summer?

Mr. Goelet—Yes.

INTRODUCING VIRGIN QUEEN TO QUEENLESS COLONY.

QUES.—What is the quickest way to introduce a virgin queen into a colony that has been queenless for several days?

A Member—I just drop the queen in on the combs, and have never lost one.

Dr. Miller—There is a possibility that next time you do that the queen will be a dead one. Don't count too much on that; if you have done it 147 times and never lost a queen you might feel pretty safe, but I would not consider you would always be safe if a colony has been queenless for several days. I will tell you one of the things that may make a difference—the time of day you do it; if you do it in the evening you will be a good deal safer than in the middle of the day. In the evening there are no other bees flying around. If you try it when no honey is coming in you will jeopardize your queen. Another thing is the age of the queen. You said, "I just drop them in on the combs and have never lost one." I don't believe you will if you drop them in while they are so young that they have just come out of the cell; a young queen is not treated by the workers as the older queen is; they don't seem to think there is anything they need care for. Let a laying queen drop in and the bees will attack her at once.

[Continued next week.]

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last. Better order at once, if you want a copy of this song.

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[Questions may be mailed to the Bee Journal, or to Dr. Miller direct.]

A Mammoth Red Clover Correction.

On page 87 I said that mammoth red clover blossoms at the same time as the other. It seems that I did not know what I was talking about. I am indebted to Hon. R. L. Taylor for the following correction in the Bee-Keepers' Review:

"In this locality the mammoth clover blossoms two to four weeks later than the June clover—so much later that the first crop bears the seed; while June clover blossoms so early that, on account of the scarcity of appropriate insects to fertilize the blossoms, the first crop yields no seed. Again, there is seldom much, if any, second crop of mammoth clover; and, hence, very little fall bloom; while, under favorable circumstances, the June clover yields a good second crop well filled with seed."

Evidence of a Mouse in the Hive.

I send a sample of stuff I pulled out of one of my hives. I pulled out about a pint March 2. I examined the hive last Saturday (March 4) and pulled out about a pint more of the same stuff, and found that the bees had cut considerable from the bottom of five combs. This is the only one of my 11 colonies in which the bees have done this. I thought at first that the mice had a hand in this, but there is no way for the mice to get into the hives. What is the cause, and how can I prevent it, if any harm is being done?

ILLINOIS.

ANSWER.—Mice. Sure. The sample sent is made up of pieces of comb smelling very sweet and nice, some of them $\frac{1}{4}$ to $\frac{1}{2}$ inch in size. If the work was done by the bees the pieces would be more nearly the size of ground coffee. You say "there is no way for the mice to get into the hive." Probably not. Neither is there any way for the mouse or mice to get out that are in there, and you probably shut the hive mouse-tight when a little fellow was in there, chuckling to himself how he had outwitted you. It is possible that you closed your hives at a time when it was cold enough for the bees to suffer a mouse in the hive without protest. The first day they can fly they will likely dispatch Mr. Mouse, unless you open the hive so he can get out of the way.

Bees on a Block Facing Hives.

1. I wish to know how I can remove bees from a pine block three feet long. I found them in a tree and sawed them out, and wish to get them into a hive.

2. I have another hive that is packed in chaff, extra outside three inches thick of chaff, except the front. On Thursday it was warm, and they came out and seemed to be greatly disturbed; they dropt on the snow and were chilled, and remained on the snow. Is it right for them to come out?

3. This hive is facing south. Should it face to the east? ONTARIO.

ANSWERS.—1. The only difference between this case and transferring from a box-hive as described in your text-book is the matter of splitting the wood. Stand the block on end upside down, and split off part at one side and then at the other side. Don't split off a piece where several combs are fastened to it, but try to take a place where two or three combs will come away with the piece split off. It may also do to split right through the middle, choosing such a spot that the combs will separate without breaking.

2. The excitement on flying after a long confinement is entirely natural, and unless the number that fell on the snow was large no great harm will come of it. It might have been a good thing if you had beaten down the snow in front of the hive. It's a good thing for them to have a flight.

3. I don't really know which is best. Some say south, some say east. When facing south the bees get the sun at the hottest time of the day. But some object to that in warm weather, because the bees will have such a hot place

to cluster in front. You can get over that by raising the hive half an inch or more when hot weather comes, then the bees can cluster on any side of the hive they like. I'd rather manage so as not to have them cluster out on either side.

Moving Bees a Short Distance Transferring Square Frame.

1. I have my bees on the winter stands, and wish to move them back about 50 feet, and 100 feet to the west of where they stand. When is the best time, and how? Is it not in March?

2. I also have one box-hive colony which I intend to transfer into the Langstroth hive. How am I to go about it, and when? Would it be better to move it first, or transfer on the old stand?

3. What kind of a hive is it that has frames 12x12 inches, running crosswise? OHIO.

ANSWERS.—1. If they are not packed so that moving would leave them without packing, then you may as well move them the first warm spell. After moving, put a board in front of each hive so as to make the bees bump against it in coming out. That will help to make them mark their location. Don't leave any hives, stands, or anything on the old location that will make it look like home to them. The more different the old place looks the better. Sometimes, however, some bees will persist in clinging to the old spot, in spite of all you may do. In that case it may be advisable to place for them a hive containing a few combs for them to cluster on, then in the evening carry these bees to some colony that is not very strong, repeating it next day or so, if necessary. If moving necessitates unpacking without packing again, then it may be well to wait two or three weeks later, even if a little more inconvenient.

2. You'll find instructions for transferring in your text-book, and you will do well to move early and not transfer till fruit-bloom, unless you prefer to wait till three weeks after swarming—a plan that seems to be growing in favor.

3. I don't know. Perhaps American.

Odd Size Frame Foundation for Brood-Chamber Bees Dying.

1. My bees are in hives which contain 11 frames, the size of each frame, inside measurement, being $9\frac{1}{2} \times 12$ inches. Do you think this too large for producing comb honey? If so, what size would you use?

2. Which kind of foundation is best to be used in the brood-chamber drawn, heavy, or brood-foundation?

3. Yesterday (Feb. 18) was warm, and the bees were nearly all out for a cleansing flight, I suppose. After they were thru flying I noticed a large number of dead bees in front of one hive. I cleaned these away and in a short time there were nearly as many more. I concluded to watch them, and for nearly an hour they continued to come out of the hive, run around for a minute or two, and then die. They were all worker-bees, and fully grown. I am sure they were killed by the bees in the hive, but why I don't know. Can you give me any information about it? NEW YORK.

ANSWERS. 1. No, not too large, but it's an odd size, and if you haven't so many that it will be difficult to change, you will do well to adopt the standard size, $17\frac{3}{8} \times 9\frac{1}{8}$, outside measure.

2. You will probably be suited with either medium or light brood. The light is more economical, the medium less inclined to sag or warp. Supported by wires or little sticks, the light will be all right.

3. A good many bees die through the winter, and will be carried out when bees have a cleansing flight. But you say the bees came out and died after running around a minute or two, which looks as if some weak "hunger-swarm" had entered, and the intruders were dispatched by the bees of the colony.

The Omaha Convention Report ran through 14 numbers of the Bee Journal, beginning with the first number in October, 1898. Now we have on hand quite a number of complete sets of that report, which we will mail for just 10 cents each. That is, 14 copies of the American Bee Journal for only a dime. There are doubtless a good many of our new readers who will be glad to get that fine report.

United States Bee-Keepers' Association.

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee \$1.00 per Annum.

EXECUTIVE COMMITTEE: Pres., E. Whitcomb; Vice-Pres., C. A. Hatch; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS: E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GEN'L MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

VOL. 39.

MARCH 23, 1899.

NO. 12.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

New York to the Front. Pres. Marks' address, as reported in the American Bee-Keeper, shows that the State Association is making real progress. The State Department of agriculture has stipulated to set aside a small fund to aid in the interchange of ideas among the bee-keepers and the promotion of apiculture in the State, and it is proposed to hold a series of bee-keepers' meetings throughout the State under the auspices of the Bureau of Farmers' Institutes.

The Union and the Association. Pres. Doolittle, of the National Bee-Keepers' Union, writes us as follows in reference to our editorial of several weeks ago:

EDITOR YORK: I take note of what is said on page 136, about "the door open for the Union," and in order that it may be kept *wide open* till the "wedding" is accomplished, I will quote a few sentences from a letter just received from General Manager Newman, in reply to mine of recent date:

"I note what you say about consolidation, and am quite willing that you should undertake the matter and work in your own way to bring it about. I am quite willing to assist in arranging details as I always have been. No one will be more pleased to have the matter amicably adjusted and the two organizations united for the purpose of doing effective work than will I. I feel that in leaving this matter in your hands it will be properly done."

As I am very favorable to the uniting of the two societies, and as far as I know all those interested are, I do not see why it cannot be accomplished as soon as the necessary details can be arranged; and who could be better fitted to arrange these details than the general managers of both organizations? I am not posted in this detail work, and am way behind with my work on account of broken bones and sickness, so I hope to be released from doing more than is

actually necessary, that the good work of uniting may go on to completion. But I will do all that is necessarily required of me to keep the "door open" till "the twain are ushered in as one flesh."

G. M. DOOLITTLE,

President National Bee-Keepers' Union.

We do not see why all details may not be arranged soon, so that the two national bee-keepers' societies will be under one banner. We suppose that a vote will need to be taken by the Union before a consolidation can take place, but we think no vote is necessary on the part of the Association, as the Board of Directors were empowered to conclude the negotiations whenever the Union decided to cast in her fortunes with those of the Association.

Nebraska State Fair and Exposition.—The State Board of Agriculture and the managers of the Greater America Exposition, after discussion of the subject, have agreed to a plan for holding the Nebraska State Fair within the Exposition grounds at Omaha, the coming fall.

The Greater America Exposition agrees to place at the disposal of the State Board of Agriculture whatever space may be found necessary for a creditable exhibit in the Agricultural, Horticultural, Dairy and Apiary buildings, and to afford proper accommodations for all the live stock that may be placed on exhibition; and to employ such officers as may be mutually agreed upon to superintend the agricultural, horticultural, live stock, dairy and apiary exhibits.

The Exposition directory appropriated \$100,000 for the organization of a colonial exhibit, and to send a representative to the Philippine islands at once.

No Honey in Southern California. General Manager Thomas G. Newman, of the National Bee-Keepers' Union, San Francisco, Calif., writing us March 10, said:

FRIEND YORK:—Here is an item from the San Francisco Daily Chronicle of March 8. It is indeed a dismal outlook for Southern California. Animals on the ranches are starving for want of food; the whole country is a parched and arid waste, with no verdure to be seen.

Fraternally,

THOMAS G. NEWMAN.

The item referred to by Mr. Newman reads as follows:

LOS ANGELES, March 7.—The bee-keepers of Southern California are much concerned about the continued dry weather. "We shall make nothing this year," said C. H. Clayton, Secretary of the Bee-Keepers' Exchange, to-day. "In good years we have realized as much as 250 carloads of honey from Southern California. Last year only 60 tons were produced, and this year there will be none. The bees are dying off very fast, and many of the bee-keepers will be bankrupt. Fully 50 percent of the bees have died since Jan. 1. No amount of rain could help us now, as far as the honey crop for this year is concerned, tho a good downpour might save some of the bees. I know of only one carload of honey in Southern California. That is being held near Perris. It is from the crop of 1897. It is held at 14 cents above the Chicago price."

This is indeed a calamity to the bee-keepers of Southern California. We only wish there was a possible way out of the difficulty, but it seems there is none. It is simply a case of "What can't be cured must be endured." Of course, should there be a good crop of honey in other parts of the country, it will not have to compete with California honey this year. So what is one locality's loss may be another's gain. But there's not much comfort in that thought for our Southern California friends.

The only thing we see for our discouraged friends to do is to draw on that limitless fund that Hon. Eugene Secor once called "the bee-keepers' bank account" HOPE. But while "living in hopes" let us trust that none may "die in despair."

The Premium offered on page 172 is well worth working for. Look at it.

The Dot Prizes and Langstroth Fund.—Finally we have the work completed on the Dot Contest Prizes. All who did not feel like contributing their amounts to the Langstroth Fund will have received them before they get this number of the Bee Journal.

The following are the names of those who gave us permission to add the amounts of their cash prizes to the Langstroth Monument Fund:

Fourteen of the 60-cent Prizes—\$8.40.

- B. W. Peck, John Michaels, W. H. Prigdon, H. F. Schultze, E. D. Lerch, Oliver Adecock, Chas. Putnam, H. E. McGreggor, O. Taylor, Rev. W. Knuff, John E. Logsdon, R. Lowrey, B. K. Lawlin, L. J. Whitney

Sixty-four of the 20-cent Prizes—\$12.80.

- E. W. Lanier, Paul F. Bratz, Alonzo Knights, G. L. Good, E. August Weiss, N. H. Vogt, Fred Brittain, Mrs. M. A. Golden, A. J. Fisher, J. W. Lane, John L. Walther, W. Bishop, John K. Frisbee, C. E. Snyder, Frank Fishell, J. D. Moflett, Jos. J. Giger, Wm. Wilson, Wm. Dambenspeck, Edmund Worthen, G. A. C. Clarke, G. W. Lawson, H. Volkerang, Stephen Lawson, Orville Jones, Thos. S. Wallace, Philto Roth, Jesse Willis, Allen Lewton, D. L. Carlton, Carlos Wheeler, A. H. Kanazy, L. K. Smith, D. E. Berry, M. S. Snow, F. W. Haynes, E. Manucke, F. C. Wiggins, Wm. Witkowsky, O. M. Pierson, Edw. Seagoin, H. D. Hill, Louis Thill, John T. Young, T. J. Green, L. P. Bolings, Stoughton Crowley, G. F. Bolder, L. P. Spring, J. P. Blunk, Geo. W. Ricker, Julius Herman, F. Sauter, Miletus Sims, A. B. Smith, S. S. Butts, Percival Golden, Wm. Stewart, H. S. Jones, Geo. F. Fall, H. Nootnagel, John W. Emmert, M. S. Patterson, F. C. Snyder

Forty-three of the 10-cent Prizes—\$4.30.

- V. W. McNeil, J. H. Tait, E. A. Crowell, James McNeill, Wm. Russell, W. I. Copeland, Rev. Chas. Horack, W. H. Cook, John Kidney, F. J. H. Davenport, C. V. Mann, Alfred E. Smith, A. Waddington, J. B. Damm, Lillian E. Trester, R. J. Purcell, Henry Willson, J. A. Tidmore, C. Lundblom, W. E. Owen, A. Snieman, L. C. George, L. G. Parvis, H. Lampan, M. M. Kimmie, Wm. Munch, W. Guthrie/Sun/Str, Ernest W. Day, J. A. Munroe, Geo. J. Stray, Aaron S. Johnson, Fred Welty, John Rogers, Wm. J. Healy, L. Staehelhausen, E. H. Bradenstine, S. M. Bragdon, J. E. Merrill, L. B. Boardman, G. E. Sutherland, Wm. Rohrig, Jos. Stephenson, John M. Hinzeker

Thirty-nine of the 5-cent Prizes—\$1.95.

- Thos. Dougherty, E. A. Chandler, E. Woodall, F. Mothershead, Alpha Wallace, W. M. Barnes, J. E. Adams, Fred D. Gibbons, Payne Bros, C. B. Howard, Edward Tanner, A. B. Cross, Jos. Unterbrink, Harry Brokaw, L. G. Clark, A. L. Heim, G. B. Mortlort, Wm. Goedker, G. Schermehorn, H. W. Roepf, Jno. W. Lyell, S. D. McClain, Mrs. I. D. Harrison, Frank L. Goss, M. F. Hathaway, W. B. McGraw, Jas. Quinn, N. Staple, Jos. Onradnak, H. C. Roberts, S. A. Dickson, O. R. Cop, Geo. E. Dudley, Frank Coverdale, M. M. Stouffer, Wm. N. Sessions, Jas. A. Stone, H. W. Savage, E. L. Hayes

Then there is a list of 18 extra contributions that we have not reported heretofore, amounting to \$13.23, as follows:

Table with 3 columns of names and amounts, including Wm. Munch (\$1.20), L. A. Syverud (.20), N. Staple (.25), Wm. Hildebrandt (.25), C. Harkness (.30), Wm. Wilson (.30), A. J. Fisher (.28), John Stroebel, Jr. (.35), C. D. Day (.20), A. B. Cross (.50), J. A. Rosson (.10), Edw. S. Goudae (.100), C. Theimann (.100), W. A. Alder (.100), L. Krentzinger (\$1.20), Mrs. N. L. Stow (2.00), Lewis J. Whitney (2.00), John A. Blocher (1.00), Total (\$13.23)

All the foregoing amounts to \$40.68. There are 100 of the Dot Contest contributors, upon which we agreed to add two cents each extra, as we would have been compelled to spend that two cents on each in order to have mailed their several amounts to them. This makes \$3.20 more. So the check which we mail Mr. Secor, who has charge of the fund, would be \$43.88. No, we will make it an even \$50.00, and contribute the difference ourselves, tho we have contributed several times before. But a \$50.00 check looks so much better than one written for \$43.88!

Thirty Poisonous Plants.—Under this title the Department of Agriculture has issued Farmers' Bulletin, No. 56. This is a reproduction, in part, of Bulletin No. 20, of the Division of Botany, sent out in July, 1898, and entitled, "Principal Poisonous Plants of the United States."

The statement is made, by the botanist of the Department, that the publication of that bulletin, instead of satisfying the demand for information on poisonous plants, has increased it, and in order to supply the innumerable requests received since its appearance, it has seemed desirable to republish the information which it contained in a condensed, less expensive, and more popular form. As this Bulletin is distributed free, those wishing it should request it by addressing the Secretary of Agriculture, Washington, D. C.

MR. R. C. AIRIN, President of the Colorado Bee-Keepers' Association, read a paper recently on "Fruit vs. Bees," before the Farmers' Institute, which was published in the Loveland (Colo.) Register, of March 8. It filled three columns, and of course was an able and interesting production.

EDITOR E. R. ROOT, in Gleanings, had this kind word to say about our new department:

"The department called 'Afterthought,' by 'Cogitator,' now running in the American Bee Journal, is a good one, and is a real addition to the Old Reliable."

THE M. RUMELY COMPANY was established 46 years ago, and has been doing business all these years at LaPorte, Ind. The M. Rumely separators and engines are known everywhere for the superiority of their construction and the uniform high quality of their work. They make compound traction engines, portable engines and semi-portable engines. In threshers they manufacture the New Rumely Separator. A full line of Dingee-Woodbury horse-powers, saw-mills of various sizes, and Maurer's Automatic Baling Presses completes the line. Every article is the complete embodiment of good material, good skill and perfect workmanship. Write them for large illustrated catalog which they will take pleasure in mailing to our readers, if the American Bee Journal is mentioned with the request.

KEROSENE EMULSION IN SPRAYING.—The value of kerosene as a material for spraying has been generally appreciated by horticulturists and others for some time, but the difficulty and uncertainty of preparing and using of the various emulsions of kerosene have prevented its general use. With an eye singly fixt on its value, The Deming Co., of Salem, Ohio, set to work experimenting for a machine that would make its own emulsion while in the act of spraying. The result is the "Weed" Knapsack Kerosene Sprayer, the "Success" Bucket Kerosene Sprayer, and the "Peerless" Barrel Kerosene Sprayer. The great success of these several machines is due to the fact that the force applied in pumping injects just the amount of kerosene desired into the spray in such a manner as to make a perfect emulsion. The amount of kerosene is easily regulated by an indicator on the top of the kerosene tank which controls the percentage of oil. The Deming Co.'s illustrated catalog containing complete formulas for spraying, in addition to descriptions of their very complete line of pumps and nozzles, will be sent on application. Be sure to mention the American Bee Journal when writing them.

DR. PEIRO, when in California last summer, learned something about the Chinamen's bee-keeping, and tells of it in the following:

One has to go from home to study some of the least known characteristics of bee-keeping. The celestial is not so much more removed from the best methods as are some of his brothers with less slant of eye and deprect cheek-bones. But as with others not governed by right ways of bee-keeping, results are equally discouraging.

A Chinaman's bee-yard offers the most variegated assortment of hives that have prevailed the last thousand years—the grass, rope cupola, hollow knot-hole, cracker-box, and beer-keg. Bees of any nationality are alike to John. The poetic Italians have no greater honor shown than the more obstreperous German. To him they all sting alike, and their fiery darts are all equally hot. He carries his fan to cool off excessive temperature, a failure in that direction always being yelled in his peculiarly high key—"Hellee!" which being interpreted in the vernacular means "Fire."

The crop of honey obtained from those arid side-hills in California is small indeed, and attended with great vexation of spirit, but I suppose the flavor is the sweeter for the trouble endured. DR. PEIRO.

Plain Sections and Fences. says Editor Root, were bought by several thousand of their customers last year, only two calling them a failure, while some others who were not entirely satisfied with them were found to have fences of faulty construction.

Don't Experiment on too Large a Scale. is the advice of G. M. Doolittle. It is needless to sacrifice a whole apiary to an experiment, as some seem to think. On the other hand, don't be too much afraid of experimenting on your own hook.—Gleanings.

To Get a Special Breeding-Queen. Gleanings advises to buy four or five queens at \$5.00 or \$10.00 each, breed from all and get a composite stock, getting the queens from different breeders so as to avoid in-breeding. Which may be very good advice for those who don't know how to get rid of their money otherwise.

Japanese Bees, according to K. Aoyanagi, in the American Bee-Keeper, are grayish-yellow, becoming darker with age, smaller, gentler, and harder than Italians. They build white comb with thin walls that does not bear transportation as well as that made by Italians. They work in rainy weather when Italians stay at home.

Threading Instead of Wiring Foundation.—A writer in the British Bee Journal says he uses cotton-thread instead of wire for fastening foundation, letting the thread be opposite on each side and slightly cutting into the foundation. The foundation is drawn out enough to hold it firm before the bees gnaw away the thread. This "needs confirmation."

Importing Queens.—W. A. Gilstrap, of California, reports in Gleanings that last year he imported six queens from Italy. Four died on the way, one was lost in introducing, and the other one absconded with most of the bees several weeks after being introduced. He thinks a trip of 20 days is too trying, and that it is better to buy of importers in the Eastern States.

Large or Small Hives. In the American Bee-Keeper, A. E. Mann favors both kinds—the large hive for a location with a short honey season, if no increase is wanted and no feeding desired; the small hive for a location with a honey-flow of long duration and the bees run for comb honey by one who gives close attention at all seasons, and also where increase is desired.

The New York Spraying Law, which went into effect July 1, 1898, is given in American Bee-Keeper as follows:

Section 1. Any person who shall spray with, or apply in any way, poison or any poisonous substances to fruit-trees while the same are in blossom, is guilty of a misdemeanor, punishable by a fine of not less than \$10.00 nor more than \$50.00.

Section 2. This act shall take effect July 1, 1898.

How Long After Infection Before Foul Brood is Bad? is a question answered by Wm. McEvoy, in Gleanings. Sometimes in a week, sometimes a year; generally less than three months. Depends upon amount of diseased honey. To become diseased, the honey must be stored in cells where foul brood matter had dried down, then other cells partly filled with sound honey may become infected by honey from the diseased cells.

Bees as Fertilizers. A bee-keeper gets less fruit from apple and pear trees three miles from any bees than from the home orchard near bees, and G. M. Doolittle advises planting bees nearer than three miles from the dilatory trees. He relates that Gregory, the squash man, tied gauze over the squash-blossoms with little squashes at their bases, and invariably the little squashes turned yellow and died. A Kansas Station Bulletin says: "An insufficient supply of bees will hinder the setting of fruit. While other insects

may take part in the carrying of pollen, the fruit-raiser must rely chiefly upon honey-bees. Experience shows that the hungry bees may fly two or three miles, hives should be within half a mile of the orchard or small-fruit patch."—American Bee-Keeper.

Wide Frames, which have been discarded by many, are strongly advocated by G. M. Doolittle in Gleanings. He sees no reason for changing, so long as he gets highest market price and more, having gotten 20 cents last fall in Boston for some of his fancy honey, when it was quoted 14 and 15 cents. Properly constructed wide frames keep sections so clean there is no need of a machine to clean them, and the tin separators he has had in use 20 to 25 years have been cleaned only once.

Strong Colonies for large results, has almost past into an axiom, yet that there are limits must be conceded. In Centralblatt is mentioned a case in which a giant swarm was formed by the uniting of several swarms, until a weight of 13 or 14 pounds was reached. The season was favorable, all colonies being very heavy in the fall. This giant colony yielded a harvest of 73 pounds of comb honey, but in comparison with others it ought to have yielded 120 pounds. A larger result would in all probability have been attained if the big swarm had been separated in two.

Making Haste Slowly.—In the American Bee Journal for Feb. 2, the editor of the Canadian Bee Journal has his attention called to the fact that he had copied half a page in his journal for January from the British Bee Journal without giving credit. In the Canadian Bee Journal for March the editor says: "We therefore hasten to make the correction," adding that his paper has never been accused of systematic pilfering. The latter statement is true, for his pilfering doesn't seem to be particularly "systematic," but it's a little difficult to understand how he has "hastened to make the correction," when it occurs two months after the omission of credit.

Examining Bees in Spring.—A discussion reported in the Canadian Bee Journal makes it appear desirable not to open too early hives for examination, as the breaking of the sealing leaves the hives cooler afterward. Mark the hives that appear light, so as to supply their wants, then it may not be necessary to disturb the others. But weight alone cannot be depended upon, as was brought out by Mr. Alpaugh. Two colonies may weigh the same—one may be light in bees and have more honey than it needs, while the other, strong in bees, may starve unless fed. The usual difference of opinion prevailed as to the advisability of stimulative feeding in the spring.

"What's the Flatter with Holtermann?" is the anxious inquiry of the editor of Gleanings. On page 106 of this journal, in an item giving a statement of the views expressed by Editor Holtermann, of the Canadian Bee Journal, with respect to no-bee-way sections, the following passage occurs:

"At the Toronto exhibition plain sections took no prizes. Sections of the ordinary kind shown there beat the sections shown by Danzenbaker at Buffalo."

The statement in that passage is a very severe infraction of the ninth commandment, if there is no mistake in what is said in Gleanings for March 1. That this Boiler may not be held responsible for misrepresentation, the following quotation gives verbatim the words of the Canadian Bee Journal: "...how is it that at Toronto, London, and Ottawa exhibitions the plain sections did not distinguish themselves by capturing the prizes on comb honey? The comb honey in the plain section was shown at Toronto, but secured nothing."

It appears, however, according to Gleanings, that plain sections were *not* exhibited at Toronto. C. E. Taylor sent some plain sections of honey that he found unopened the last week of the fair in Manager Hill's office, where he opened the lot and showed it to Mr. Holtermann. This being brought to the attention of Mr. Holtermann, he said in his paper:

"Again at Toronto plain sections were entered and sent to the exhibition. I saw them there, but thru an oversight they were not judged."

This does not satisfy the editor of Gleanings, who wants evidently to have Mr. Holtermann say in plain words that plain sections were not on exhibition at Toronto, and had no possible chance to take any prizes. Of course that will be the easiest way out, if it is the truth.

Root's Column

PLAIN SECTIONS.

Who said they were not Money-Makers?

Read this Unsolicited Testimonial:

I have tried the fences the past season; and if any season would show up the poor side of an appliance for bees or bee-hives, the last one surely would. I watched the outcome of using fences very carefully, and note the following: Two hives of bees, side by side, were given the second super each, one containing fences, the other old-style sections 4 1/2 x 4 1/2, no fences or separators, both having stored the first supers nearly full. The one containing fences stored nearly double the amount that the other did. Now, I found this to be the case all over the apiary; in fact, the bees seemed to give the preference to supers containing sections and fences, no matter whether they were next to the hive-body or two or three supers above. I won't say why this is so, but will leave that for you. As to the matter of cleaning fences, it is not a very great task, as only the uprights have to be cleaned; and the pleasure of having neat and even sections of honey compensates for whatever extra time is used.

W. T. SHERMAN.
Millard, Wis., Feb. 13.

And now read this, from that careful and conservative bee-keeper.

J. E. Crane, of Middlebury, Vt.:

Will the evolution of the honey-box bring the plain section into general use? I believe it will. One dealer in Washington told me he would pay three cents per pound more for the 4x5 plain-section honey than for the old-style sections. Indeed, I was offered two cents per pound more, for 5,000 pounds of clover honey, to be delivered next fall, than I have been receiving of late for my best grade of honey, if put in plain 4x5 sections. In New York I inquired of Mr. Segelken for his plain section honey, that I might compare it with that in old-style sections. He said he had very little left in plain sections, as such lots were picked up first by retail dealers, who preferred them to the old-style sections. I found the same true in Albany, N. Y., where I stooped to look over the honey. As these retail dealers are not in the supply business, I thought their opinions worth recording.

We now have about half a hundred more like them.

Keep Your Eye on this Column,

It may save you dollars.

The A. I. Root Company MEDINA, OHIO.

GENERAL ITEMS

Bees in Good Condition.

Last year was almost a failure here. We got but 900 pounds of extracted honey and 200 pounds of comb honey. The season bids fair this year. Six hundred pounds of the extracted was dark honey-dew, and the comb honey also. But 300 pounds of extracted in the fall from asters, was very fair. As it is a pretty warm day, I shall make an examination of the bees.

J. WILEY MOUNTJOY.
Anderson Co., Ky., March 5.

Small Loss in Winter so Far.

I had 102 colonies of bees packed for winter, and I think they are wintering fairly well. I saw them Feb. 25, and I think there were but seven dead ones in the lot. I expected to lose very heavily, for the weather was cold and no bright, warm days so they could fly, until the middle of February; since that time they have had a very fair show.

I like the American Bee Journal very much indeed. I don't think anyone should try to keep bees without one or more good papers—the more the better.

Jos. S. SECCOMB.
Cayuga Co., N. Y., March 5.

Satisfied with the Business.

I have 200 colonies all in good shape. I have been feeding flour for three weeks, but my bees are getting natural pollen now from the pussy-willow. I produced 10,000 pounds of section honey last year. My honey is sold here and at Spokane; some of it went to the miners.

I have been in the bee-business for many years. I use the Langstroth-Simplicity 8-frame hive. I am satisfied with the business, and also truly satisfied with the American Bee Journal, to which I credit my success. May it lay on my table as long as I live and keep bees, is my prayer.

ISAAC HAYS.
Yakima Co., Wash., Feb. 27.

Not a Promising Outlook.

The outlook for honey this season is not very promising. Many of the fruit-trees, flowers, etc., were in bloom when the February freeze came, and all were killed. Just think of it, zero this far south! We have never had it so cold before. The bees were breeding up fast, but that stopt them for awhile, and weak colonies were lost. I have made a Manum swarm-catcher, Daisy foundation fastener, section-press, and an Alley queen-trap, besides hives, covers and bottom-boards. This is all done in my spare time at nights, etc. I have a small shop and a good variety of tools, and my brother has a saw-mill and planer, so I don't have much trouble about lumber. Success to the American Bee Journal.

LEE ELDER.
Harrison Co., Miss., March 7.

An Anti-Robber Block.

I notice a great many questions in the Bee Journal about stopping robbing, and at the Colorado Bee-Keepers' Convention it was discussed, and none of their theories were ever a success with me. I have a plan of my own that I have never given to the fraternity, and I have never failed to stop robbing. I have stopt them from robbing queenless colonies when they had half of the honey carried out, introduced a queen, and everything was all right.

I take a block of wood somewhat longer than the entrance, 1 1/2 inches square, and saw four or five notches in it large enough for a bee to go in and out. Place it in front over the entrance late in the evening

SECOND-HAND Sixty-Pound Cans For Sale Cheap.

Second-hand 60-pound Cans, two in a case, we offer, while they last, in lots of five or more cases (10 cans) at 40 cents a case, f.o.b. Chicago. They are in good condition. Better order at once if you want some of them. Address,

after the robbers quit work, or early in the morning before they come out, and they never offer to go in the small holes, while the bees of the hive will work in and out through the small holes without any difficulty. Almost all of the robbers will alight on top of the block, and if they can't get it away they will soon give up. Now I have never had a colony robbed since adopting this plan.

The above is a diagram of the block.
Clearfield Co., Pa. G. W. BELL.

Weather Hard on the Bees.

Yesterday morning it was 15 degrees and this morning 14 degrees below zero here. It is hard on the bees. They have had but one good flight since cold weather came to stay, and did not fly from all the hives then. **E. D. HOWELL,** Orange Co., N. Y., Feb. 11.

Hard Winter on Bees.

This has been a very hard winter on bees. My neighbors tell me they have lost nearly all of their bees. Most of them are wintering on the summer stands. Mine are wintering nicely in the cellar. I have lost only one so far out of 41. **C. L. BURLEY,** Calhoun Co., Iowa, March 11.

Bees Seem All Right.

Bees seem to be all right. They commenced carrying in pollen March 10. We have had the coldest February ever known in Kentucky. I thought the bees would all perish, but I believe they have come through in about as good shape as usual. Score another victory for the golden Italians; they winter as well as any bees. I have tried them all. **W. S. FEEBACK,** Nicholas Co., Ky., March 14.

Wintering All Right.

I have 22 colonies of bees wintering all right so far in chaff hives. It was 30 degrees below zero here. I got about 900 well filled sections from the 22 colonies last year. I get the Bee Journal every Thursday. It is all right. Long may it live. **N. RASMUS,** Nemaha Co., Kan., March 14.

Half the Bees Starved.

One-half of the bees in this locality are starved to death. I saved 14 colonies so far. I think as long as we have "seed" we should "sow" and "try again."
JOSEPH UTTERBRINK, Putnam Co., Ohio, March 12.

A Difference in the Honey.

I was a little puzzled in the work of my bees the past season. There were only two of the 10 of my colonies that I got any surplus honey from. They stood within a foot of each other. The honey from one was of a thin quality and of an inferior taste, so that none of my family except myself would eat it. The other was first quality and gathered, so far as I know, at the same time. There was the same difference between the sealed and the unsealed. I would like Dr. Miller to explain the cause of the difference. **J. C. ARMSTRONG,** Marshall Co., Iowa, March 4.

Long, Hard Winter Sweet Clover.

It has been a long, hard winter, and the bees don't seem to do much good any more here. Mine did not get more than what will keep them. I got only a very little honey from two or three colonies. I sowed

a little white clover and Alsike on a piece of ground last year. By the way, is white clover and sweet clover the same? When I bought the clover I askt if he had any white sweet clover, and he said it was all the same—that all the white was the same kind, there was no difference.

WM. Y. STACKHOUSE.

Chester Co., Pa., March 14.

[White or Dutch clover and sweet clover are not at all alike. The former grows only a few inches high, while the latter grows all the way from two or three feet to 10 feet in height.—EDITOR.]

A Little Experience—Facing Hives.

I started the fall of 1894 with one colony. It wintered all right. In 1895 I increast the colony to two; in 1896 to nine; in 1897 to 18; and in 1898 to 25. The increase is rather slow, but sure, as the winter loss is small. I winter them on the summer stands, but have the hives well packt with chaff and sawdust on the outside, of course. I have five, six or seven hives in a group, so I can use 12 or 14 foot boards for packing-boxes. About 3/4 of my hives face east and the rest west or southwest. The former had only one good flight from the middle of November to the middle of February—about three months' confinement; while the latter had three flights, and have had perhaps only half the loss in bees on the bottom-board. So that is a valuable object lesson as to which way to face hives during winter, and tallies with the advice of both Mr. Doolittle and Mr. Dadant.

JOS. M. REITZ.

Buffalo Co., Wis., March 11.

Colonies Strong and Lively.

I have 300 colonies in good condition at this date in winter-cases, two in a case. They are quite strong and lively on warm days.

I saw some time ago that foul brood was in Schenectady County, and likely to spread, but I hope it may be stayed.

E. H. STURTEVANT.

Washington Co., N. Y., March 14.

Report from Indian Territory.

My bees wintered well. I lost only three colonies out of 80. I wintered them on the summer stands, with super on, and packt with hay and leaves.

I increast from 34 colonies to 80 last season, and secured about 2,000 pounds of surplus, about one-half comb and balance extracted.

I sell my honey in the home market at 15 cents for comb and 10 cents for extracted.

I always speak a good word for the American Bee Journal. I prize it very highly, having taken it ever since I kept bees, and shall continue to do so. I hope this may be a good year for our business.

J. T. HAIRSTON.

Cherokee Nation, Ind. Ter., March 3.

Report of the Season of 1898.

Dec. 1, 1897, I put 204 colonies in the beehouse, and March 18, 1898, I took out 203, losing one by starvation. I offered them for sale for \$2.00 a colony, but did not reduce them low enough so that I could handle them and do my farm work, so I doubled them down to 150 colonies; then I thought I would put sections on them and that would check them some from swarming.

We had an abundance of white clover bloom, but the bees gathered no honey from that source. Then basswood was the next to bloom and that lasted about four days so that the bees could work on it, on account of rain. Those that had the hive full of brood and honey stored one super each of 24 one-pound sections of basswood honey; and they were but a small share of the apiary. Then there was nothing more to store surplus honey from until buck-

A Little Gold Dollar and Our Big Poultry Book

represent about equal value. This book contains every thing that it is necessary to know to succeed in the poultry business. All about Incubators and Brooders, the best kind and the best way to handle them; thoroughbred poultry, with illustrations of each breed and a complete line of poultry supplies. We send it to all inquirers on receipt of 10 cents in stamps.

Page & Lyon Mfg. Co.

NEW LONDON, WIS.,

Operates two Sawmills that cut, annually, eight million feet of lumber, thus securing the best lumber at the lowest price for the manufacture of **Bee-Keepers' Supplies.**

They have also one of the **LARGEST FACTORIES** and the latest and most improved machinery for the manufacture of **Bee-Hives, Sections, &c.**, that there is in the State. The material is cut from patterns, by machinery, and is absolutely accurate. For Sections, the **clearest and whitest Basswood** is used, and they are polishd on both sides. Nearness to Pine and Basswood forests, and possession of mills and factory equipmt with best machinery, all combine to enable this firm to furnish the **BEST GOODS AT THE LOWEST PRICES.**

Send for Circular and see the prices on a full line of Supplies.

WESTERN FARMS.

A beautifully illustrated paper called "The Corn Belt" is published every month and contains a quantity of interesting information about the farm lands west of the Mississippi River. Pictures of all sorts of farm scenes in Iowa, Missouri and Nebraska. Personal experiences of farmers who went to those states from the East years ago. The handsomest farm paper published. Send 25 cents for a year's subscription to **THE CORN BELT, 209 Adams St., Chicago.**

Think of the Future. Don't Rent. Establish A Home of Your Own.

Don't fail to mention the Bee Journal when writing advertisers.

wheat came into bloom, so I thought, as they swarmed, I would fill the balance of my hives for winter. By so doing I had 216 colonies to put into the bee-house, besides three that I disposed of in the fall, and they stored a little over 2,000 finish sections of honey, besides several hundred partly-finish ones. I fed some of the unfinished ones to the bees, extracted some, and sold some in the home market.

Bees are doing well. On the 12th of this month I strolled down among them. The thermometer on the outside showed eight degrees below zero, and I took it in among the bees for 10 or 15 minutes, when it rose to 46 degrees above zero.

ANDREW M. THOMPSON.

Allegheny Co., N. Y., Feb. 13.

Poor Season Last Year.

The last season was a poor one in this section of South Carolina, tho I am hoping for a good season this year. The bees are now bringing in pollen. The weather is not favorable for them—it is a little too windy. I am working for comb honey. I did not get much honey of any kind last year, for the season was too poor. I am thinking that I will run for extracted honey when I get a few more bees. It will not pay me to buy more now. My bees are all hybrids. I want to Italianize them this year with the finest Italian queens. My stepmother has a few colonies of black bees that are regular, old-fashioned blacks—as black as coal tar.

The first bees I ever owned I found in a tree about four years ago. I have found some since, and bought some, so I now have a fair start in bees. I have learned a good deal about bees the last few years. I have taken the Bee Journal eight months, and I think that is worth twice the subscription charged for it.

I have tried sowing buckwheat here, and it does very well. I planted mine too late last season, and the frost killed it before the wheat had ripened. It kept the bees a lot, for they would work on it when all other flowers had failed.

JULIAN HALLMAN.

Lexington Co., S. C., March 6.

Discouraging Prospect for Honey.

I notice in my last Bee Journal that some of the bee-keepers are telling of 25 and 30 degrees below zero. Here in Clayton Co., Iowa, the first of February we had 17 days in succession that the thermometer did not get above zero, and it was down to 35 degrees below some of the time; and this was without any snow on the ground. The ground is frozen six feet deep. If the bees and clover stand that I guess they will stand almost anything.

I started in the winter with 130 colonies, but have only 105 left now, with prospect of losing a good many more. The ones I lost had plenty of honey in the outside combs; as long as they had honey over the cluster they were all right. When that was gone it was so cold they could not move sideways, so they starved right at the top of the hive.

When they talk about large hives I am with them, only I want my hive large up and down.

I have moved to town, leaving my bees on the farm four miles from here. I expect to drive back and forth, and take care of them this season, altho the prospect for a honey crop is very discouraging.

F. B. FARRINGTON.

Clayton Co., Iowa, March 12.

Cold Weather for Bees.

EDITOR YORK:—I send you one of our country papers so that you can see what kind of weather we have had the last two weeks; and Monday, Feb. 13, there was blinding snow flying, we could see no distance, and it was very cold. With it all I did not forget my bees, but after breakfast at 6 a. m., and my farm-stock was fed and cared for, my two boys and I went to work to get the bees in a good, dry cellar. We

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.]

made a fire in it and got the thermometer to register 46 degrees, and they seemed as happy as fighting chickens; and, by the way, I felt good, too, in knowing that they were all alive. Fifty-two colonies, all with plenty of honey except one which I soon fixt; almost all of them got up to the top of the combs with plenty of honey on each side of them. I lookt in some of the hives a few days later when they were in the cellar, and found the bees on each side of the hives on the honey enjoying themselves.

Last Monday killed a great many bees. My brother, S. J. Hammond, lost 10 out of 100 colonies, and another neighbor lost two out of eight.

The last few days have been warmer and the snow is melting slowly. Yesterday the thermometer was 45 degrees in the shade.

We have had snowdrifts 10 feet deep. I helpt two days last week to shovel roads open to get out. With all the snow and no regular mail the good old Bee Journal got here at the regular time.

L. A. HAMMOND,
Washington Co., Ind., Feb. 20.

Bees in Good Condition.

I have eight colonies of bees in good condition, considering the cold weather they have gone thru, as they have been on the summer stands all winter and the thermometer registered 16 degrees below zero.

I am using the 12-frame Langstroth hive. I like it very well. I am delighted with the reports from other bee-keepers in the Bee Journal, and am well pleased with the paper itself.

W. M. HITCHCOCK,
Lonoke Co., Ark., March 3.

Bees All Right so Far.

My bees are all right so far. I examined some in February after the cold spell, and found some brood and also some hatching drones. Those few I had in the cellar I put them out-doors, as it was too damp for them inside, and they are doing all right.

M. BEST,
Lucas Co., Ohio, March 3.

A Believer in Big Hives.

In 1868 I commenced working with bees and tried to commence right. I read Gleanings awhile, and then took the American Bee Journal, which I read yet. And now what I don't know about bees of course is not worth knowing!

The colony I had on the scales all last summer made a gain of 54 pounds in eight days while basswood was in bloom; that was the only gain for the season here. Many colonies starved before winter, and many others are dying now. I have lost 6 colonies, and have 104 with plenty of stores in the middle stories on the summer stands.

Let Mr. Doolittle have small hives and Mr. Dadant large hives, if they are suited with them; but Gallup and I want big hives. For the last 10 years I have used the 3-story 15-frame Langstroth hive, which makes a big hive. Now when there comes nectar, so the bees can gather from 10 to 20 pounds a day for two or three weeks, those hives will hold it, and the bees don't have to look around for more room or a new home. They won't swap such a hive full of honey for nothing. And the honey can remain until thoroly ripe, without being in the way of the bees, and always makes the best honey when extracted. My bees never swarm from these hives. I hope others will try the big hive and report, from different localities. I feel that Dr. Gallup and I are on the right track for the most honey and best queens. (Say, Doctor, let's stay with it and convert the world to big hives and good queens.)

GEO. W. RIKER,
Lucas Co., Iowa, Feb. 25.

Convention Notices.

Texas.—The Texas State Bee-Keepers' Association will hold their 21st annual convention at W. R. Graham & Son's, Greenville, Texas, the first Wednesday and Thursday in April, 1899. All interested are invited. No hotel bills to pay.
W. H. BURNETT, Sec.

Utah.—The Utah Bee-Keepers' Association will hold their regular semi-annual convention April 8, at 10 o'clock a.m. in the city and county building, Salt Lake City. A full program in the interest of the industry will be presented, and all bee-keepers are cordially invited. Among the subjects to be considered will be the purchasing of supplies, the disposal of our products, and the best method for the protection of the industry. It is desirable to have every county represented, either personally or by letter. Questions are solicited.
MILL CREEK, UTAH. J. B. FAGO, Sec.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, March 7.—Fancy white comb brings 13c, and there is a good demand for it. No. 1 white is also wanted at 11 1/2c, depending upon quality. Lower grades of white, amber and most colors range from 8 1/2c, with dark and buckwheat 7 1/2c. Extracted white clover and sage, 6c; basswood and alfalfa, 7c; amber grades, 6c; buckwheat, 5 1/2c. Beeswax, 27 1/2c. Market generally healthy in tone with best grades of honey scarce. K. A. BURNETT & Co.

DETROIT, March 9.—Fancy white comb scarce and higher and we now quote it 13 1/2c; No. 1, 12 1/2c; fancy dark and amber, 10 1/2c. There is considerable poor honey in the commission houses which is offered at 8 1/2c. Extracted, white, 6 1/2c; dark, 5 1/2c. Beeswax, 25 1/2c. M. H. HUNT.

KANSAS CITY, March 10.—Fancy white comb, 13c; No. 1, 12c; amber, 11c; dark, 10c. Extracted white, 6c; amber, 5c; dark, 4 1/2c. Beeswax, 25c. C. C. CLEMONS & Co.

NEW YORK, March 8.—Fancy white, 12c; No. 1 white, 10 1/2c; amber, 9c; buckwheat and dark, 6 1/2c. Comb honey is pretty well cleaned up now and we expect to dispose of the balance of our stock during this month. Excepting California there is not much stock of extracted on our market. Demand is fair at unchanged quotations. Beeswax, 27 1/2c. HILDRETH BROS. & SEGELKEN.

SAN FRANCISCO, March 9.—White comb, 9 1/2c; No. 1, 7 1/2c; amber, 7 1/2c. Extracted, white, 7 1/2c; light amber, 6 1/2c; dark, 5 1/2c. Beeswax, 24 1/2c.

Market is not favorable to buyers, more especially for desirable extracted stocks of which are decidedly light. Comb is in moderate supply, and has to depend almost wholly on local custom for an outlet. Quotable rates remain as previously given.

BOSTON, March 10.—The demand for comb honey is very light, with full stock on hand. We quote our market: Fancy white, 13 1/2c; A No. 1, 12c; No. 1, 11 1/2c; light amber, 9 1/2c. No demand for buckwheat. Extracted, white Northern stock, 7 1/2c. Beeswax quiet at 27 1/2c. BLAKE, SCOTT & LEE.

OKLAHA, March 13.—The stock of comb honey in this market is very light. There are not over 500 cases of all grades in first hands. Demand continues fairly active. Fancy white quotable at 13c; choice, 12c; No. 1 amber, 11c. Extracted well cleaned up. PEYCKE BROS.

BUFFALO, March 10.—There is only very little dark poor honey in our market, which is selling at mostly 5 cents. Some strictly fancy white comb honey would bring about 12 cents. Little, if any, here. No extracted to mention. Fancy pure beeswax, 30c. BATTERSON & Co.

CLEVELAND, March 9.—Fancy white, 13 1/2c; No. 1 white, 12 1/2c; A No. 1 amber, 10 1/2c; No. 2 amber, 9 1/2c; buckwheat, 8c. Extracted, white, 7c; amber, 6c; buckwheat, 5c. A. B. WILLIAMS & Co.

MILWAUKEE, March 2.—Fancy 1-lb. sections, 13 1/2c; A No. 1, 12 1/2c; No. 1, 11 1/2c; dark or amber of old, 7 1/2c. Extracted, in barrels or kegs, white, 7 1/2c; dark, 5 1/2c. Beeswax, 25 1/2c.

Since our last report we have had a very good market for honey, and the demand has been very good for all grades, especially for sections of the best quality, and the demand is good now and small supply. We encourage shipments of best comb. Extracted, fair demand. A. V. BISHOP & Co.

The Afterthought.

The "Old Reliable" seen through New and Unreliable Glasses.
By "COGITATOR."

WHAT ABOUT THE "GOLDEN" METHOD.

Now that the Golden method has been fully set forth, what shall we say about it? Rather a matter for trial than a matter of criticism. It is a superior auger if it *bore better than other augers*, otherwise not. Plausible enough to demand a show, and in points "ouplausible" enough to demand watching. Watch a little out as to what the bees do with their pollen those first five days. Mr. G. well says that the method saves an immense number of new hives and fixings, which of course need to be figured in as reasons in favor.

Cogitator once ran a number of hives several years in which bee-space chambers (full of bees usually) surrounded the sections entirely top and sides. They were not so they could be used as climbways at all. The inventor was only seeking to give *confidence* to the little misers, and secure evenness of temperature. I don't know that this plan secured the storing of more surplus than otherwise would have been stored, but it seemed as if it did. So I cogitate that Golden's spaces help on somewhat, in the same way as those of mine, but not for the reason which he assigns.

"KNOCK-DOWN" EVIDENCE ON HONEY-DEW.

That knock-down evidence that leaves secrete honey-dew without any insects at all (page 98) has been given before. But 'Tater is just scabby and dirty enough not to believe it, either for 'tother chap, or for this chap. Of course, Mr. Nash is sincere and all right—but then, there are experimenters, and *experimenters*. The commonest kind are capable of proving things that aren't so, in the most lovely fashion. He wiped off the surface sweat, but not that which had penetrated the pores of the leaves. This last modicum of it worked out in time. What we are askt to believe is too much like believing that an amputated arm would spurt out blood 24 hours afterward. Still, 'Tater may some day have to hunt his hill, and admit that there sometimes are circumstances under which leaves pour out sweet of themselves. Freshly-cut stubble certainly does sometimes—in immense quantities—but that is more like having the *stump* of the arm bleed after an amputation.

A LITTLE OLD-FASHIONED FAITH NEEDED.

"On hand with money and influence to defeat." Yes, sir; that's the kind of an age we are living in. No law to make a man sell his products for just what they are is going to get thru without an awful fight—and another one to enforce it. See Mr. Abbott's article, page 99. But did you ever think how much a little genuine, old-fashioned faith

faith in the ultimate triumph of the Kingdom of God—helps people in such a contest as that? Sometime, not far off, in the sweet by-and-by, things will not be sold under false names.

PRICE OF SUCCESS A HARD PROBLEM.

"From daylight to dark, year in and year out the price of success in almost any calling." (Page 102.) That's another thing the sweet by-and-by will abolish. At present we are tied up in this contradictory fix. First, excess of labor offering, so that some must go idle. Second, long hours for all that do work and dreadfully long hours for most who get independent jobs. I don't know how to solve this problem of too much and not enough. If I did (and told) that would be politics, and I should have to stop.

UNQUEENING TOO MUCHIE FUSSEE.

Interesting to see that so strong a hand as F. L. Thompson is not satisfied with the unqueening-in-harvest methods. (Page 103.) Too much adkee time fuss, fuss, fuss, when a body hasn't time to fuss. And at best it depopulates the colony undesirably.

SWARMING WITHOUT INCREASING.

While successful non-swarming seems to be no nearer than the millennium, swarming without increasing does seem to be getting down to a cheerfully accurate science. Mr. Thompson's last contribution to it seems excellent. Put the hive that has swarmed at-top the new one, pretty closely shut up, yet with a perforated-zinc passage leading below, for young workers, and an escape at the door, available for drones and young queens. Soon all the population have left; and administration is in order on an empty hive—and a swarm from the full one, perchance.

WHEN TRAVEL-STAINS ARE NOT TRAVEL-STAINS.

Quite important is that boiling from J. E. Crane, on page 106. Certainly travel-stains can't be travel-stains literally if they go clear through. Undoubtedly they sometimes do and sometimes do not. Whether real travel-stain is rare or not is the question—let's find out. Current opinion has been that travel-stain is a very common thing.

STINGLESS BEES OUGHT TO BE MORE CLEVER.

The information about the stingless bees of Old Mexico, on pages 109 and 110, deserves a more prominent place than it got. Three or four pails of honey sometimes from a colony of the little trigonas, which are individually only 3/16 of an inch long. If we were going to keep them for honey we should object to their style of storing honey in hollow bullets. Why can't they be clever, and put their honey, as well as their brood, in civilized comb?

TWO DIFFERENT RANKS OF BEES.

Bees (as to their storing) are divided broadly into two different ranks. The one prepares its honey by manipulation, and processes in which comparatively little is added to it; the other trusts mainly to secretions which they add to it, usually some acid. All the bees we are familiar with here belong to the first rank, but elsewhere there are a multitude of species of the second rank. And, if I am right, no two are exactly alike as to the character and palatableness

of the chemicals they pour in—some nice acid honey, and some abominable acid honey. Mr. Andrews (page 110) has struck a good kind. Possibly the decided novelty of its tamarind-like deliciousness may stir up a market for it sometime. And you see he has a paper-making bee that stores honey—and also belongs, like our bees, to the non-chemical rank.

NO HUMAN HOGGERY WANTED.

If six respectable business men should consent to act as witnesses in such a disgusting show of human hoggerly as that proposed on page 124, I should be surprised. Let's be decent—and gobbling down (of any kind of food) a pound and a half in a minute and a half is not decency.

APIS DORSATA—GOOD EXAMPLE TO FOLLOW.

You hit 'em well, Mr. York, on page 120, about those howls against *Apis dorsata*. Let the big bee have judgment on the merits (or demerits) of its own case. What's the use of forever looking at it thru the specter of Frank Benton—and then going into a spasm? F. B. is certainly not a pet at the American Bee Journal office, yet our Editor's position is as you see. Right good example to follow.

"YEARS HAVE COME, AND PAST AWAY."

We're growing old, we're growing old. For 15 consecutive years Thomas G. Newman has held the helm of the National Bee-Keepers' Union—with signal ability and success. Of them that were given him to defend he lost none. Especially we should remember that his victories have redounded to the protection of all the rest of us, outside the Union. And now he says this must be the last time. Thus to us all, sooner or later, there comes the time for us to sing—

"I do not pass this way again."

GRADES OF HONEY TO HAVE THEIR "PICTER TOOK."

And so that breezy and irrepressible Colorado convention is going to have photographs prepared illustrating its grades of honey. Tiptop idea. Language can be twisted with dreadful ease; but "photos," while not always competent to straighten out folks who have a twist in their moral natures, are not easy to pervert. And how pleasantly photographing would relieve us of impossible grades of honey!

COLONIES RUN FOR COMB VS. EXTRACTED.

Two similar colonies, one run for section honey and one for extracted, and the former will close the season with plenty of honey below, while the chances are that the brood-frames of the latter will be very light. Comrade Aikin makes a good point when he shows this up, on page 115.

CUBA'S "SKEETERS" AND SNAKELESS PORTO RICO.

Queer about those mosquitoes in Cuba that Mr. Poppleton tells of, on page 114. Does cowardice affect all animate creation on that flowery and languid isle? That both Spaniards and Cubans fought by shooting off their guns and falling back, we've heard before; but "skeeters" that shoot off their music at a distance, and then flee to cover, are a novelty.

Porto Rico's exemption from snakes may be from haying (some time in the remote past) a very dense population of snake-eating people, often hungry to bed; but that Cuba, with its immense swamps, should have no venomous snakes, and few of any kind, is curious indeed.

BEWARE OF BEES THAT BUILD TOO MANY QUEEN-CELLS.

If we obey Mr. Doolittle and all learn to be queen-breeders, perhaps Dr. Gallup's method, page 114, will serve as a good way to begin—strong unqueened colony made still stronger by shaking in hosts of bees—not a too-old larva left in the hive anywhere—plenty of eggs, both foreign and domestic, in center, and also on each side. Not surprising that he got 36 at a lick under such conditions, even from a first-rate colony. Beware of the strain of bees that builds two or three dozen cells under circumstances where ordinary bees would build only half a dozen—degenerates, Cogitator thinks, backsliding into bumble-beesism.

GET HIM AT LAST!—SWEET CLOVER TRICKS.

Glad we've got him. I'm as happy as the aged husband was when his wife (after 40 years of nightly search) found a sneak-thief under the bed. After many years of multitudinous denials from the claps, who didn't sow sweet clover by the roadside, behold the man! It was honest-looking Mr. Stolley, page 113. But I hope community will decide that the fellows who didn't confess need "massacreing" more.

It is a mitigating circumstance that he "squeals" on

his favorite plant, and tells us a bad trick of it that we had not heard before—sprinkles itself all over the natural prairie-mowing grounds, and gets dead and dry like hazel-brush just as the late prairie-grass is ready to cut.

Indian ponies had to be taught before they would eat corn—white man's ponies have to be taught before they comprehend sweet clover. Very pretty aphorism.

COGITATOR.

A Crisis in California Apiculture.

BY PROF. A. J. COOK.

WE have all read of the person who "when she was good she was very good, and when she was bad she was terrible." At present that seems not an inapt characterization of Southern California. In good seasons like that of 1897, from 100 to 500 pounds of honey are often secured from each colony, and that even with three or four hundred colonies in the apiary. No one will say that that is not "very good." Yet close upon this excess of sweetness comes 1898, with a severe drouth, and no nectar-secretion by the flowers, and no honey product from the bees. The provident bee-keeper did not take too severely from the bees the previous season of abundance, and so his colonies were well supplied, and past the season with no loss. Less careful bee-keepers removed so much of the honey that no margin was left to bridge over a year of honey-dearth, and so, long before 1898 had past, the bees were victims to greed on the part of the owner thru starvation.

But now comes 1899, and all prospects point to a greater drouth than that which confronted us a year ago. As yet we have only four inches of rain, whereas we need many times that amount. Even the bees of our most expert and careful bee-keepers are short of stores, and unless rain comes soon, or liberal feeding is practiced, there will be few bees in Southern California to greet the incoming century as 1900 dawns upon us. Very likely floods of water and floods of honey will come with the new century, if the bee-keepers are ready to avail themselves of the restored conditions of prosperity.

It is, then, a question of great practical import to the bee-keeper, how he may best and most cheaply hold on to his bees, and maintain them in health during the protracted famine. To keep full colonies breeding, and feed enough to sustain all, is too costly, and not wise at all. Simply working to keep queens, and just sufficient brood-rearing and bees to keep her in good thrift and vigor would seem the wisest plan. Could not this end be met, and at the same time economy be served, by securing at the same time young, vigorous queens in all cases where such were not already in the hives? Nearly all of us have at times taken a queen with a pound or less of bees, and in a few weeks have had a good colony. Is this not a good year to make nuclei a main or entire feature of the apiary? Why not rear queens in small nuclei until we are sure we have only young queens, and all from our best stock?

Then, why not keep our bees reduced so as to save the energy of the queen, and at the same time save to the utmost in the expense of feeding? Scant stores usually lessens the working energy of queen and workers alike, and so a minimum of food, consistent with the well-being of the bees, will save alike in the expense and in the wear and tear of both queen and bees. I believe a little labor in reducing the bees to nuclei and in requeening where such a course is desirable, may save much, and pay good profits in the time spent.

It is very probable that 1900 will be a season of rains and honey, and fortunate indeed will he be who is ready to avail himself of the riches that come so generously at such seasons.

PRESERVING THE EMPTY COMBS.

There is one more thing that should be kept in mind. Good combs are very valuable, and, with an abundance on hand, colonies can be built up with great rapidity when the time comes to prepare for the harvest. It is very wise, then, to look to it that the moths do not ruin the combs set

free by the formation of nuclei, as suggested above. These should be kept in very close boxes, where it is cool, so that they will not melt down, or else hung in cool, lighted rooms so as not to touch each other.

I have kept combs over, year after year, in both these ways. In practicing the first method we must be sure that no moth-eggs are on the combs, or, if we are uncertain, we must examine, and if necessary must use sulphur fumes to destroy these comb destroyers.

In one respect California is very fortunate in her misfortune; when these seasons of disaster come to us, we know for weeks long before the season opens, that no harvest will come, and so we can plan to make the best of our ill-fortune, and can set about some other work to busy our hands and fill the larder.

THE FROST—ANOTHER CALAMITY.

They say calamities never come singly, and Southern California seems to illustrate the truth of the saying the present season. Two weeks ago we had a bad freeze-up. The thermometer reached successively, for four nights, 27 degrees, Fahr., 25 degrees, Fahr., 20 degrees, Fahr., and 26 degrees, Fahr. In the East that would be thought mild, but here in our citrus groves it borders on the disastrous. The oranges and orange-trees seem not much injured, but the lemons, and the lemon-trees, are very greatly damaged. The trees look as if the blight or a fire had been among them. It is also reported that bees suffered, but as they could fly days during the time, I think it was more probably depleted larders that victimized the bees.

Los Angeles Co., Calif., Feb. 24.

Cold Winter for Bees—Other Matters.

BY MRS. L. C. AXTELL.

I FEAR it has been too cold for bees in this region, as they were not strong in numbers, each colony being rather small. If the winter had not been colder than the past few winters, I think they would have wintered all right, and possibly they may yet where they were packed with chaff. Ours had filled their brood-nests very full of honey, and the bees lookt and acted healthy, so we concluded to let them go without uniting them, as uniting is

Mrs. L. C. Axtell.

not a very satisfactory piece of business, and certainly not very desirable work.

The bees that are in the cellar I think will be all right, even if the colonies were small. There seemed to be in our whole 155 colonies scarcely any that we could call strong; yet, as I said before, they lookt and acted healthy late in the season, but just about the time they began to gather fall honey they had dwindled down weak. The cause, I think, was from getting so much peach juice. The last of

July and first of August our peach-orchard was alive with bees on the early peaches; they would not only suck the juice out of the ripe ones, but from those that were rotting. Often we would see a peach almost covered with bees, and they seemed stupid sometimes, not sick, but loth to leave the peach, and often would stay all night on the peaches. But on looking into the hives and in front of them, there were no dead bees, and as they were almost out of honey we thought it best to let them alone. I now think it would have been a good plan to have fed them some white sugar each day, to mix in with their peach-juice. The honey in the hives had a decided peach flavor, and was rather dark.

When the fall flowers blossomed they almost let the peaches alone, so by the time the neighbors' seedling peaches ripened they did not bother them much. It was the early budded kinds they bothered the most. One kind, especially after several days of rain and damp weather, rotted badly, the bees working on them to their harm.

I am glad that we took great pains to pack those out-of-doors with chaff, the very best we knew how, and set them up from the bottom-board about an inch, as we always do.

This has been the coldest winter here since 1885, when the mercury went down to 28 degrees below zero. Last week Thursday it reacht 30 degrees below, and every night since has been from 15 to 25 degrees below, so we will probably have no peaches another season. I hope the peach-juice will make no difference with the wintering of the bees; I think they did not store enough to affect their winter honey, but I think it caused them to dwindle some, but not so much as they would have dwindled if they had not gotten the juice, as they had failed to fill the hives in the spring full enough to carry them thru and cause the queen to keep her hive full of bees. The peach-juice caused the queen to go to laying eggs in the fall two or three weeks sooner than she otherwise would have done. But the juice seemed to sicken or cause the old bees to become less in numbers, altho I could see no dead bees anywhere.

Last spring opened up promisingly, and we got everything in readiness for a crop of honey, but the weather was so cool, wet and cloudy that flowers, especially white clover, failed to secrete nectar. We had but two swarms, and they were more supersedures than natural swarms; but half a dozen colonies or so went to work in the sections, so we secured only about 30 or 40 pounds of honey from the whole apiary of 155 colonies. I think we would not have had that if it had not been for the honey in some of the supers we put back on the hives in the spring. I think we got the least surplus honey the past year we ever did, tho we had to feed the bees scarcely any—a few dollars' worth only—before white clover bloomed.

Warren Co., Ill., Feb. 15.

Prices of Honey Not Made by Law(?).

BY G. M. DOOLITTLE.

Do not conclude that it is because something is out of joint politically that you get such a low price for your honey, or have such a hard time in the world.—Rev. E. T. Abbott, in American Bee Journal.

It is impossible at this time to form any idea of the probable effect of Cuban honey on the American markets. If the present duty should be removed, it is easy to see that it might be a serious competitor, if it were sold for less money, as it could be, with the duty removed. So far Uncle Sam has made no move to annex Cuba; and unless he does there is no reason why the duty should not remain on Cuban honey; and even if annexation should take place, it does not necessarily follow that Cuban honey will come here free.—E. R. Root, in Gleanings.

Now it seems to the writer that law has nothing to do with increasing the price of the produce of any individual or class of individuals. While the law has nothing to do with high or low prices, it does have something to do with preventing fraud and deception.—Rev. E. T. Abbott, in American Bee Journal.

While the price of almost every agricultural commodity has declined greatly during the past 30 years, official salaries and taxes have increased. This applies to local, State and national affairs, and no political party pledges itself to reduce the big salaries nor abate the high taxes.—J. C. Stephenson, in Free Press.

Will the reader carefully go over the above quotations from three noted men, until they are perfectly familiar with what is said, and what would be the logical result of each when carried to its legitimate end? Having done this, let us look at the matter a little to see if it is a fact which Mr. Abbott is stating when he tells us what he does about the price of produce (honey) not being made by law.

God made the world and placed in it, and on it, all that was necessary for all men, and this part is included by the one word "land." In the true economic sense, the fish of the sea, the fowls of the air, and the bees in their wild state in a cave in the rocks or hollow tree are included in the term land, as well as the forests, mines and earth. But man could not use or appropriate any of these things without an

effort of muscle or brain whereby any of the natural gifts of the Creator were changed from the natural form to something desired by man, or some portion of the human family. And this effort of the hand or brain is called "labor." And the production of labor on land is called "wealth," because it is something desired by some portion of the human family. And thus it comes about that *labor alone*, aided by the forces of nature, produces *all* wealth.

W. Z. Hutchinson finds a wild swarm of bees in its native home in the forest, and by labor of muscle and brain plans and makes a modern hive with supers, into which he places said wild swarm, and in due time thru his labor he has several cases of nice comb honey (wealth—something desired by man) stored away in his shop. He next sends it to a distant city to be sold on commission, and the carrier, the commission man, the retailer, the book-keeper, etc., are all laboring on land, from an economic standpoint, just as much as Mr. H. was, in producing the honey. Thus, to understand a thing fully, we must look at it in all of its bearings, if we would come to a right conclusion in any matter, and not make statements which "will not hold water."

We have seen that *labor alone* produces *all* wealth, but mere *effort* of head or brain does not constitute *labor*, but *effort which is productive* of anything desired by the human race or any portion thereof. If, when Mr. Hutchinson has that honey all nicely crated, I go and work all night digging a hole thru the well under his shop, and just before morning carry off part of the crates of honey stored there, tho I may put forth much *effort* in so doing, yet, as by that effort nothing has been produced which is desired by any member of the human family, such effort is *not labor*.

And if "some Napoleon of finance" sits down in his office, and by the most arduous effort thinks out a plan and gets laws past whereby he is able to steal a railroad, form a trust, or accomplish a corner in the money market, by which he is enabled to *reduce the price of honey* at the expense of bee-keepers, or cause them to pay a *higher freight rate* on their honey, so that he can live by "his wits," as is often expressed, that effort, no matter how arduous it may be, is *not labor* in the economic sense. And, notwithstanding what Mr. Abbott would have us think about nothing being out of "joint politically," history proves that nearly *all* of our laws are made *politically*, and nearly *all* of our *political laws* are made for these "Napoléons of finance," to the robbery of bee-keepers and others, thru prices made by law. And to the man who "sees clearly," these politically-made laws are so much more oppressive to bee-keepers than any adulteration of the past or present, that the adulteration matter, which has been in every bee-keeper's mouth during the past decade to account for his "misery," is but a "drop in the bucket" compared with the robbery coming to bee-keepers thru our *unjust system* which prevails, by laws *bought thru* by our Napoleons of finance, and sanctioned by such bee-keepers as Rev. E. T. Abbott, and 99 out of every 100 of the rest of us who call ourselves apiculturists.

Let us look a moment: According to statistics of a few years ago, there were living in the city of Pittsburg, Pa., 65 men whose aggregate wealth was \$700,000,000. This wealth had practically been accumulated within 20 years. Now, if I read Mr. Abbott aright, he would claim that, because these 65 men had "climbed up the mountain side" faster than either he or I had done, or rather, nearly reach the top without climbing at all, they had not hindered us any, for "law has nothing to do with increasing the price of the produce of any individual." Have they hindered us any? We shall see.

It is but reasonable to suppose that it would take a higher order of ability in each of the above 65 men to manage their business than is required in us bee-keepers who labor hard for a whole year with an income of \$1,000 or less annually to show for it. But would it require an ability greater than is required in the Secretary of the Treasury of the United States? Yet that officer receives only \$8,000 a year. But suppose we allow them the salary enjoyed by the President of the United States—\$50,000 a year—and that they are each worth that much to the country; and supposing that they had saved all their earnings for the 20 years, the accumulation of the 65 men for that time would have been \$65,000,000. As their accumulations were \$700,000,000, it is evident that they have received from the bee-keepers and laborers of the country during the 20 years \$635,000,000 in addition to what they would have earned with a salary equal to the President. How did they get it? We have seen they could not have earned it, for the most of them did no kind of labor except of the kind I did in

securing Mr. Hutchinson's honey; certainly not more than to earn the \$50,000 salary we have allowed them.

As we have already seen that *no wealth* can come into the world except by *labor on land*, it *must* have been taken from others who *had* earned it, thru our unjust laws. And yet Mr. Abbott tells us "law has nothing to do in increasing the price of the produce of any individual!" And these 65 men are only samples of thousands of others who are daily gathering from the bee-keepers of our land, and from other laborers, thru their *law-made* prices, till at the lowest estimate \$1,000,000,000 are being taken from the rank and file of our people who produce *all* wealth, and given to the few each year, until 25,000 men own one-half of the wealth produced by 70,000,000 people. This wealth is taken without giving any return in labor of either hand or brain. It is being gathered from bee-keepers, farmers and professional men, from the laboring men, from the women in cities toiling at starvation wages, and from helpless children; gathered from all of these and poured into the lap of the *law-protected* favorites, whose wealth no man can comprehend. And yet Mr. Abbott evidently would claim that this is no hindrance to those from whom it is taken!

Think of a scheme brought forth by "wise heads" of our Government which gathers from its starving paupers and hard-worked bee-keepers, gifts to pour into the laps of the millionaires! How do the people furnish this money? By the extra price paid on all the *law-protected* goods they buy. E. R. Root gives a little hint regarding how the law works, and J. C. Stephenson tells how the "produce" of salaried officials and taxes are *law-increased*.

In the Bee-Keepers' Review (page 17), R. L. Taylor would have us think that Gen. Alger got his millions by "saving \$3.00 stage-coach fares in walking 40 miles and back again;" but informed bee-keepers know that *law-protected lumber* made every bee-keeper using hives tributary to his riches, by paying a higher price for the lumber they had to use. Had Mr. Alger commenced to walk with Christ on the plains of Bethlehem, and been enabled to walk 40 miles each working day ever since, at the same rate Mr. Taylor tells us of, he would still have 227 years to walk before he would have gotten *even one* of his millions he now possesses.

It seems strange to me that bee-keepers can see *so much* in adulteration, and spend time and money in fighting it, without a word about the *unjust system* in our country which is "slaying its thousands to where adulteration slays its tens." Adulteration is bad enough, God knows, but would it not be well to get this "big beam" (our unjust system) out of our eyes, so that we can "see clearly" to pick out "the mote" (adulteration) from our national affairs?

Onondaga Co., N. Y.

Value of Queens in the Spring.

BY C. P. BADANT.

THE publication of several articles from me about large hives, in Gleanings and the American Bee Journal, has brought forth a number of remarks from different writers, and I have noticed that great stress was laid upon my statement, that in the spring the queen is the most valuable part of the colony. I had resolved to say nothing more, being rather tired of a discussion in which I take no interest, as I know it is out of the question to change our critics. But the remarks on page 170, quoting Mr. Taylor, have brought the matter afresh to my mind.

There seems to be a denial of my assertion that the queen, in the spring, is the most valuable as well as the most expensive part of the colony. Mr. Taylor says, "Air is of most especial value, yet is it not the least expensive?" What I wish to say is only a repetition of what we all know. In the spring a bee-keeper may have empty hives, empty combs, queenless colonies, but he never has queens without bees, colonies without hives, unless he has bought them at great expense and great risk from a warmer latitude. It is therefore a fact, and a fact which does not bear discussion, that the queen is the *most valuable* as well as the *most expensive*, since it is the *most scarce*, requisite of a good colony, and the *sine qua non* of a living colony of bees for the opening season.

Air is inexpensive, but if Mr. Taylor were deprived of air, he would be ready to pay a big price for it within a few minutes.

The Premiums offered on page 206 is well worth working for. Look at it.

CONVENTION PROCEEDINGS

Report of the Chicago Bee-Keepers' Convention.

BY A SHORTHAND REPORTER.

[Continued from page 182.]

Next was read a paper written by Mr. C. P. Dadant, of Hancock Co., Ill., on

Producing Extracted Honey on the Mississippi River.

It is with the greatest pleasure that I open a subject which is probably more familiar to me than any other question pertaining to bee-culture, as we have made the production of extracted honey on the Mississippi River a constant practice for a quarter of a century or more. It is only necessary to state our experience and our reasons for finding it more profitable than the production of comb honey in the same circumstances.

It was only after some 10 or 12 years of experience with both comb and extracted honey, begun immediately after the invention of the honey-extractor, that we finally concluded to devote our apiaries almost exclusively to the latter.

Every apiarist who has read up on the subject is aware of the great cost of comb to the bees. It is by digesting honey that the bee produces wax, which is produced much in the same way as fat on farm animals, and costs the bees about the same proportion of honey as fat costs of grain—an amount variously estimated at from 7 to 15, and even 20 pounds, according to the more or less favorable circumstances in which the insect or the quadruped finds itself. The production of extracted honey does away in part with this expenditure, or, in other words, with the enforced production of comb during the harvest.

When the colony is populous and the crop begins, as it very often does in a sudden way, the bees often find themselves short of room to deposit their honey, even before they have become prepared to produce any comb; for it takes some 24 hours before the transformation is made, and until wax is produced and comb is built, a part of the bees at least, have to remain idle and lose the opportunity of going to the field. And if comb has to be built right along to lodge the crop, it is a very important item of expense to them, both in time and honey. It is therefore not astonishing that bee-keepers should have found in practice that more than twice as much honey could be produced, if the combs could be furnished ready to be filled by the bees instead of having to be built by them.

Some comb honey producers who think that this question has been overestimated, say that the bees naturally produce beeswax anyhow, and that this beeswax must be used by them or wasted; but they do not stop to think that a certain amount is needed at all times, even when full combs are given to the bees, to repair such places as may have been damaged by the handling, or to lengthen the cells that have been cut down in extracting, and also to seal the cells when they consider the honey sufficiently ripe to be sealed.

I do not know whether the bees are really compelled by Nature to transform some honey into wax if they will or not during a heavy honey-flow, but I can hardly believe the quantity thus produced can be very great in ordinary circumstances; for I have never seen any beeswax wasted except in accidents to the bee-hive, such as the breaking down of some of the combs by heat and weight, when the bees are all compelled to fill themselves to the utmost with the wasting honey. In such instances I have noticed that they would attach it to the walls of the hive, as if expecting to use it later on.

At any rate, our experience, which was gained by a number of years of production on hundreds of colonies, has clearly evidenced to us, and to our entire satisfaction, that the teachings of the masters—who advanced these ideas, let it be remembered, long before the invention of the extractor—are in accordance with the facts. Experience proved that by saving our combs with the use of the extractor, and returning them to the bees the following season to be used and filled over and over again, we could produce more than twice as much extracted honey as comb honey.

Extracted honey is hardly ever less than half the price

of comb honey on any market, and very often it may be sold for two-thirds of the value of comb honey. Besides, it is much safer to ship, less easily damaged by railroad handling, and when it has to be kept over from one year to another, the risk of its losing any of its quality or salableness is much less than with comb honey. We know this also by experience, for we have often found it advisable to keep honey from one year to another to secure a greater price for it. In years of great crop the price is low, while the seasons like the present (1898), when the crop seems to have been universally a failure, much better prices may be secured; besides the satisfaction one has of keeping one's customers by being able to supply them.

We have often kept extracted honey one, two, three, and even four years, without loss; while with comb honey the leakage and the danger of the invasion of the moth make it very unadvisable to hold it beyond the season of its production.

But the advantages above-mentioned are not the only ones that are connected with the production of extracted honey when compared with that of comb honey. A most important point to be considered, or at least one that has had to our mind a great deal of weight, is in the easier and more thorough prevention of natural swarming. When the number of colonies under the control of one man has reached into the hundreds, the results in honey are of much greater value than the results in swarms, which can only be sold with difficulty. Then, if swarming can be almost entirely prevented much less capital is needed in the way of empty hives. The bees need less watching, and the cost of production is lessened. With large hives, of course, and plenty of room, and a judicious use of shade and ventilation, swarming, even with comb-honey production, may be kept within comparatively reasonable limits, but with an additional supply, liberal and unlimited, of empty combs ready to put on the hive at a moment's notice, there is no need of any fear of swarming except in unusual circumstances, or with careless management.

But to my mind, and with the results of past experience, I cannot too strongly urge the importance of using hives in which the fertility of the queen will have full scope, and supers which will not cramp the bees for space in a few days. One must remember that the little 24-pound super is entirely inadequate for a strong colony that is to be supplied with an unlimited stock of empty comb.

I have no patience with the extracting-super made to fit the ordinary section-case. A super 4½ inches deep gives too much labor in the handling. The supers that we use with our large hives hold from 40 to 60 pounds of honey, according to the season, for much depends upon how the bees fill them. But one super is not enough, tho' in some bad seasons each colony may not fill even this space. We keep an average of two supers or more full of empty comb for each of our colonies, and we have had many instances where even three supers were placed on populous colonies and filled several times over during one season.

Another item in favor of extracted honey is that it costs less labor; for when the combs are once built there is nothing to do in the way of preparation for each crop. The labor of folding sections and placing in the foundation-guides, or strips of comb that are necessary to secure salable, straight combs; the putting in of the sections, the constant oversight to make sure that not too great a number of sections will remain unfinished and unsalable, the annoyance of seeing a half-filled case deserted by the swarming of the colony are not fully compensated by comparative profits.

The labor of removing combs or supers for extracting is no greater than the removal and putting in shape of the same crop of comb honey, and extracting is additionally remunerated by the cappings, which, when rendered into beeswax, will go very far towards paying the help employed.

The best grades of honey probably bring the best prices when in the very nicest shape in the comb, but the inferior grades, such as honey-dew, buckwheat, boneset, etc., have no value for the table, and can only be used in the liquid extracted form by bakers, tobacconists, brewers, and others.

C. P. DADANT.

Dr. Miller The fact is, if every one were to believe with Mr. Dadant and I wish he were here, as he is one of the nicest men you ever met if everybody were to believe with him, then everybody would produce extracted honey, and it looks inconsistent for him to urge the production of extracted honey; if he were looking after his own welfare he ought to say, produce comb honey, so he would have the market for extracted honey himself. I suppose there are a

great many different opinions about it. I think some Nebraska bee-keepers will tell you they produce three times as much extracted honey as comb. No doubt they are telling you the truth. There are others, again—I have in mind Mr. Aikin, of Colorado—who will tell you he can produce nearly as much, if not altogether as much, comb as extracted; circumstances are different in different places, and I think it is one of the things that will settle itself, and I doubt very much if it would be wise for us to try to decide, because both extracted and comb honey are needed in the market; like everything else, if I find I can make more money by producing one than the other, I am settled by that, and so each one will settle the question largely for himself.

PRODUCTION OF COMB HONEY AND EXTRACTED.

QUES.—How many are there who produce principally extracted honey and how many principally comb? ANS.—Extracted honey, 3; comb honey, 13.

AVERAGE LIFE OF BEES.

QUES.—What is the average life of the bee?

Dr. Miller—That depends upon what kind of a bee it is; if it is a queen it will perhaps live on an average of about two years. I think there have been some cases in which it has been pretty satisfactorily settled that queen-bees have lived as long as six years. They are often superseded in less than a year from the time they emerge from the cell; sometimes I have had them superseded in a few weeks. Very likely queens are superseded oftener than you suppose. A common thing is for a queen to be superseded after the time of swarming; it may not have occurred to you that every queen that dies in the natural condition of affairs, if you don't meddle with them, is superseded. The worker, in the busy season, will average about six weeks; the life of the worker depends upon the amount of work it does. The drones I cannot tell you much about; they will last usually until there is a stoppage in honey.

(Continued next week.)

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

The Wells' Two-Queen System.

Please describe as nearly as possible how the two-queen system is handled and worked by producing comb honey. I would like to try the two-queen system the coming season.
NEW YORK.

ANSWER.—I don't know what you mean by the two-queen system, unless you mean the Wells' system, which has been practiced to some extent in England. The main feature is having two colonies side by side in a large hive with a division-board between them, a lot of holes being burned through the division-board, and when the harvest comes the bees have access to the same super. Some like the plan and some don't, and the British Bee Journal thinks it not an advisable plan for the majority. So far as I know, no one has reported a success with the plan in this country.

Varieties of Bees.

1. Kindly differentiate between the following varieties of bees, especially as regards appearance, but also as regards honey-getting and temper: 3-banded, 5-banded, golden and leather-colored Italians, Albinos and Adels.

2. Prof. Cook in his Manual speaks well of Syrians. Do subsequent experiences confirm or disprove his good opinion of them?
JOHNNY BULL.

ANSWERS.—1. The original pure Italians that came from Italy were 3-banded, that is, the first three bands of the abdomen next the thorax were yellow; breeders in this country by selection have secured workers with five yellow bands, some having all the bands yellow, these last being called golden. Some of the imported 3-banders are of a darker color, and are called "leather-colored." Albinos among bees are much the same as albinos among the human

race—bees which have been so bred that the coloring-matter is somewhat lacking. Adels are bees to which that name has been arbitrarily given, just as you might breed from some of your best bees and call them "Johnny Bull Bees." As to honey-getting and temper, the 3-banders being the most fixt type may be perhaps most generally relied on as a whole class for gentleness and industry, while in the variant types some may be good and others bad.

2. Very little is said about them of late, making it somewhat doubtful as to their confirming generally his good opinion.

Bees Don't Always Die of Foul Brood.

Do all bees that die and have dead brood in the hive die of foul brood? Is the honey fit for family use? I have lost two colonies that way this winter; both had plenty of honey.
WASHINGTON.

ANSWER.—No, thousands of colonies die and leave dead brood without there being any foul brood in the case. The honey left in such hives is all right for table use, unless the bees have had diarrhea and have daubed the honey.

Cubic Inches in Eight Frames—Queen-Excluders.

1. How many cubic inches inside the frames of a dovetailed hive?

2. What style of queen-excluding honey-board do you use between the hives?
IOWA.

ANSWERS.—1. The outside dimensions of the frame are 17³/₈ and 9¹/₈, making the inside measure something like 140 square inches. The width of an 8-frame dovetailed hive is 12¹/₂ inches, and deducting from this about ⁵/₈ for dummy and space leaves 11¹/₂. That makes about 1,610 cubic inches as contents inside the frames.

2. Wood-zinc, when any are used, but no excluders are generally used between my hives and supers.

Substitutes for Natural Pollen.

1. I have five colonies of bees. The queens stopt laying about Sept. 1. Will my bees live till spring? There seems to be plenty alive yet, but there are also lots of dead ones.

2. We have some warm weather just now (Feb. 20), and my bees go to the feed-lot ¹/₂ mile away, and carry corn-meal home. Will it do to put a box of meal closer to the hives for them?

3. I will have to feed my bees this spring. Can I put candy or syrup on a stand close to the hives so that they can all help themselves on warm days?
KANSAS.

ANSWERS.—1. There is nothing unusual in anything you mention, and your bees will probably come out all right.

2. Yes, it will be a nice thing to give them something of the kind one to ten rods from the apiary. They will probably like it a little better to have ground corn and oats; but as soon as they can get plenty of natural pollen they will pay no attention to the substitute.

3. Yes, put it a rod or more from the nearest hive.

Making Nuclei—The Golden Method.

1. I intend to increase my number of colonies the coming season by dividing. My plan of doing it is this: I have 14 old colonies, and want to increase them to 28 in all. So I thought I would take 14 of my new hives in which I want to hive the new swarms, and make a nucleus in each, by putting a frame of brood and eggs and one of honey in each hive, and then contract the inside of the hive with a division-board so as to keep the bees which I intend to put into the hive confined to the side of the two frames. How many bees will I have to put into a hive? Will a pint or so do? And will these bees rear a queen from the eggs given them? Do you think a nucleus formed in this way will be all right? Would it be safe from robber-bees?

2. In the American Bee Journal of Jan. 5, G. M. Doolittle gives his plan of making nuclei. Is his plan the same thing? There is one thing that isn't clear to me in his article, altho it may be very plain to an expert in bee-keeping. Does he use one of the old colonies in making a nucleus? That is, does he make room in an old colony by using a division-board, and then put the two frames in the place partitioned off, with the rest of the old colony on the other

side? or does he take a new hive? The reason I think Mr. Doolittle makes his nucleus in an old colony of bees is because he says, "The greatest advantage in full, regular-size hives comes in not having our nuclei robbed out occasionally."

3. How long before swarming shall I make these nuclei?

4. I intend to use light brood-comb foundation this year. Do you think it will hold the bees without sagging if I stretch four wires across the frame?

5. In Mr. Golden's articles I see he makes the entrance in the bottom-board of the hive. Would it not also do just as well to make it about five to six inches right above the lower entrance of the hive? Our hives are 14 inches wide, with an entrance cut from the front board at the bottom, the whole length of it.

IOWA.

ANSWERS.—1. No, I'm sorry to say your plan wouldn't be all right, for in one respect it would be exceedingly bad. If you put in a hive a frame of brood, another of honey, and a pint of bees, they may protect themselves against robbers, and they will be pretty sure to rear a queen, but the chances are that the queen will be a very poor affair. Don't think of having a queen reared anywhere but in a strong colony, at least until after the queen-cell is sealed. Such a nucleus as you speak of may do providing you give it a sealed queen-cell (you mustn't give the queen-cell till a day or two after the nucleus is formed, unless it is formed from a queenless colony), but it is better to have brood in two frames, a good share of it sealed brood, and enough bees to thoroughly protect the brood after the old or field bees have deserted the nucleus and gone back to their old home.

2. I don't think Mr. Doolittle had in mind anything different from a nucleus such as I've been talking about. No, he certainly does not mean to have the nucleus in a hive with a full colony, but means the nucleus alone to be in the hive. I've read over carefully what he says, and I don't see how he could have made it plainer. That not having nuclei robbed has nothing to do with having other bees in the hive; in fact, it wouldn't work if other bees were in the hive. Look on page 2, at the paragraph beginning, "To help the reader to understand," and you'll see that when the nucleus is at the east side of the hive the entrance of the hive is entirely closed the whole width of the hive except an inch at the west side of the hive. A robber doesn't like to enter at that west side and then run the gauntlet clear across to the east side before reaching anything to rob. I think this idea is original with Mr. Doolittle, and it's valuable.

3. Nothing is gained by beginning too early. Wait till about the time bees want to swarm, at least till they are very strong, and have your queen-cells sealed before forming any nuclei.

4. You will not be likely to have any trouble.

5. I don't know; but in following any one's instructions it's well to follow them to the letter. I have never practiced Mr. Golden's plan, so I cannot speak from experience.

Super Covers Wax-Scales on Hive-Bottom—Queen Clipping—Stimulative Feeding, Etc.

1. Is it necessary to cover the sections in a super? If so, what kind of covering would you prefer?

2. In using a board cover over the sections, how would it do to have $\frac{1}{4}$ -inch strips nailed or tacked on the underside at each end of the board, allowing a $\frac{1}{4}$ -inch space over the tops of the sections? With such an arrangement would as much propolis be deposited?

3. Are the wax-scales that fall to the bottom of the hive ever used by the bees?

4. Do you use clamps to hold the supers to the hive-body? Do you think it would be advisable to do so?

5. Where could I buy some Langstroth frames with finished combs in them? and what would such combs be worth?

6. Do you clip the wings of your queens?

7. Do you practice stimulative feeding in the spring?

8. Where so much increase is not desired, would it be safe to unite a swarm with a colony which had cast a swarm some time previously? In such a case would the bees have to be scented?

SUBSCRIBER.

ANSWERS.—1. Principally on account of convenience, I prefer to have no cover except the flat board cover of the hive.

2. Such an arrangement would hardly suit you so well as the one in common use. In that the super is made deep enough so that the tops of the sections come within $\frac{1}{4}$ -inch of the top of the super. Less propolis is deposited in a $\frac{1}{4}$ -inch space than in one through which a bee cannot pass.

3. They are probably used in propolizing, for cappings, and for aught I know for building combs.

4. I never heard of any one using them or thinking them necessary.

5. I don't know. I think I have seen them advertised for sale, but not for a long time.

6. One of the first things I do each year after it becomes warm enough to handle bees safely, is to look through each hive to see if its queen is clipped, clipping all found with whole wings, and throughout the rest of the season each young queen that commences laying is clipped the first time it is convenient.

7. Not to any extent.

8. Some have used and advocated the plan, and I think without scenting.

An Electrical Swarm-Notifier.

The enclosed clipping is from the New York Herald of Sunday, Oct. 16, 1898. It refers, as you will see, to an electrical device which announces the advent of a swarm. As I have never seen anything in the Bee Journal about this interesting invention, can you give me any light on the subject?

WOODLAW.

[The clipping reads as follows:—C. C. M.]

What has been called the "pleasant occupation of living bees" has been made even more pleasant by an electric invention which obviates the necessity of keeping a watch on the hives at swarming-time.

The basis of the apparatus is the conversion of the wing-motion of the swarm into power. As the bees swarm out they cause two small, easy-swinging doors to open outward. A little hammer, which rests upon these doors when closed and is connected with a battery, drops, as the doors swing open, upon a small metal leaf, and the electrical connection thus effected rings a bell in the bee-grower's house.

ANSWER.—Another correspondent has sent the same thing. I don't know whether anything of the kind has really been tried, or whether it is a creation of some reporter's imagination. It might be difficult to arrange it so the alarm would be given when a swarm issued and only then. For if a mass of bees rushing out should make the bell ring, the same thing might occur if a sufficiently large number of bees were leaving and entering at their regular work. Still, it might be so arranged as to be a success, but I'm afraid the expense would be such as to make it unprofitable. A rather expensive apparatus would have to be attached to each hive. An arrangement somewhat akin has been used to some extent, which has the advantage that one simple arrangement does for a whole apiary. It is one or more wires stretched, connected with a telephone at the house. When a swarm issues, the number of bees striking the wire gives notice at the house.

York's Honey Almanac is a neat little 32-page pamphlet especially gotten up with a view to create a demand for honey among should-be consumers. Aside from the Almanac pages, the forepart of the pamphlet was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample for a stamp; 25 copies for 40 cents; 50 for 60 cents; 100 for \$1.00; 250 for \$2.25; 500 for \$4.00. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

The Omaha Convention Report ran through 14 numbers of the Bee Journal, beginning with the first number in October, 1898. Now we have on hand quite a number of complete sets of that report, which we will mail for just 10 cents each. That is, 14 copies of the American Bee Journal for only a dime. There are doubtless a good many of our new readers who will be glad to get that fine report.

Langstroth on the Honey-Bee, revised by the Dadants, is a standard, reliable and thoroughly complete work on bee-culture. It contains 520 pages, and is bound elegantly. Every reader of the American Bee Journal should have a copy of this book, as it answers hundreds of questions that arise about bees. We mail it for \$1.25, or club it with the Bee Journal for a year—both for only \$2.00.

GEORGE W. YORK, Editor.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY,

118 Michigan St., Chicago, Ill.

ONE DOLLAR A YEAR.

SAMPLE COPY FREE.

[Entered at the Post-Office at Chicago as Second-Class Mail Matter.]

United States Bee-Keepers' Association.

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., E. Whitcomb; Vice-Pres., C. A. Hatch; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GEN'L MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

Place and Date of Next Meeting:

Philadelphia, Pa., September 5, 6 and 7, 1899. Every bee-keeper is invited.

VOL. 39. MARCH 30, 1899. NO. 13.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

The Illinois Foul Brood Bill, we learn from Secretary Jas. A. Stone, of the Illinois State Bee-Keepers' Association, was reported back to the Senate by the appropriations committee, with the recommendation that it do pass. Mr. Stone now wishes us to urge Illinois bee-keepers to talk or write to their senators and representatives, and try to impress them with the importance of this law to give us the protection that we have a right to. We hope that all will act upon this suggestion *at once*. Just overwhelm all the legislature at Springfield with letters, urging the passage of the Foul Brood Bill. *Do it now*, as an adjournment will take place in about two weeks.

Evident Signs of Growth in Bee-Keeping, Editor Root considers the occasional large editions of bee-papers and the increase of subscribers to some of the leading periodicals. Then the dozen supply factories (against the three or four three year ago) are nearly all working on full time, and several over-time. He thinks this tends to show that honey is becoming more nearly a staple.

The Intense Cold Spell the last end of January and first half of February aroused general fears that there would be a wholesale loss of bees all over the country. Fortunately the cold spell was immediately followed in most places by a warm spell that allowed a flight, thus saving the bees.

The Langstroth Memorial.—We have received the following acknowledgement from Mr. Secor:

FOREST CITY, IOWA, March 21, 1899.

GEORGE W. YORK, Chicago, Ill.—

Dear Sir:—Your favor of the 18th, enclosing check for \$50, to cover the amounts kindly donated by Dot Contest contributors to the Langstroth Fund, which amount was generously augmented by your own contribution, has been received.

There is in sight about \$275 for the Langstroth memorial, which amount ought to erect a very respectable shaft with suitable inscription. I hereby thank every one who has helped to make the memorial possible.

Allow me to invite suggestions for an inscription to be engraved on the stone.

The following has been prepared by the committee, and is herewith submitted for approval or criticism.

Yours truly,

EUGENE SECOR.

The inscription referred to by Mr. Secor as having been prepared by the committee, reads as follows:

Inscribed to the Memory of the

REV. LORENZO LORAIN LANGSTROTH,

"FATHER OF AMERICAN BEE-KEEPING."

By his affectionate beneficiaries in the Art; who, in remembrance of the services rendered by his persistent and painstaking observation and experiments with the Honey-Bee, his improvements in the Hive, and the charming literary ability shown in the first scientific and popular book on the subject of Bee-Keeping in the United States, gratefully erect this monument.

Rest thou in peace. Thy work is done.
Thou hast wrought well. Thy fame is sure.
The crown of love which thou hast won
For useful deeds shall long endure.

"We Be Brethren."—The size of hives has been discussed of late in the different bee-papers with much spirit. Editor Hutchinson occupied several pages in copying from Gleanings and the American Bee Journal some of the writings of the chief disputants—Messrs. Doolittle and Dadant—and remarks:

"There is one very pleasant thing about this discussion, and that is that all who have taken part in it are gentlemen. They are fair, honorable, and polite. To me it is a great comfort to argue with such men, knowing that the closing of the discussion will find us still warm friends."

The New British Bee-Papers.—Speaking of journalistic courtesy among bee-papers, the Britishers are not a whit behind their Yankee cousins, if indeed they do not lead. The British Bee Journal, speaking of its new rivals, Bee-Chat and the Scottish Bee-Keeper, says:

"Courteous in tone, and beyond reproach in substance, the respective editors are apparently quite conscious of the fact that successful bee-journalism is only possible when kept clear of personalities, and conducted—as between readers and themselves—in the spirit of gentlemen."

"When Discussion Should be Cut Off," is the heading of an editorial in the Bee-Keepers' Review. Referring to the American Bee Journal, he says that a discussion as to improvement in bees "started a discussion regarding the soundness of evolutionary doctrines. When it reached this stage, Bro. York thought it had past beyond the province of a bee-journal, and he cut it off. I think he had a perfect right to do this." He thinks evolution, trusts, and a thousand other things that are proper subjects for discussion should not find a place for discussion in bee-journals; that many subjects may be so related to bee-keeping as profitably to be noticed up to a certain point in a bee-journal, and it is the business of the editor to decide when the point

is reacht beyond which further discussion will not yield a profit. He says :

"If I have ever written anything giving the impression that I believed any one who *wisht* should be allowed to write *what* he wisht, and *how* he wisht, and that it then became the duty of the editor to publish it, and to allow discussions to run on and on, and to wander where they may: if I have ever given such an impression, I wish to correct it."

But he believes in giving every one a fair show, and allowing a discussion to go on, even if it does make the fur fly, "so long as *the original subject is kept in view*, and personality and abuse do not take the place of argument, and each round brings out new facts and views."

An Interesting Plan for Conventions was followed at the Brantford, Ont., convention, reported in the Canadian Bee Journal. "The members spoke in consecutive order, and not otherwise unless to ask a question. When all had spoken, or declined to speak, a few minutes were allowed for general discussions. The first question began with the first gentleman in the circle, the next with the second gentleman, and so on all around the circle." So good a plan might well be imported into the lands lying south of Canada.

Amalgamation.—The Editor of Gleanings thinks that now is *the time* for a "wedding" to take place between the National and the "United States Union" (will he please take note that the latter is not a Union but an Association?). seeing that two of the main props of the National refuse to take office again, and that the Manager accepts his office for the last time. It is quite probable that a "wedding" will be announced before very long.

A New Word "Alright" has been persistently used by one or two bee-papers on this side, and now its appearance in Bee-Chat, an English bee-paper, raises the question whether it is the beginning of another spelling reform, or whether it is a word for which there is some present or past authority.

THE LEAHY MFG. Co.'s catalog for 1899 has come to hand. It quotes prices on a full line of bee-supplies. Their advertisement will be found regularly in the Bee Journal.

EDITOR HUTCHINSON has gotten up a very nice 20-page advertising pamphlet describing and illustrating "Some Characteristics of the Bee-Keepers' Review." A copy lies on our desk, and will be appreciated for its artistic beauty.

MR. W. A. PRYAL, of Alameda Co., Calif., writing us March 16, said :

"We have just had two days heavy rains in northern and central California, and prospects of more. Good crops are assured. The storm may have reacht the south. The rain is worth millions to us."

MR. THOMAS G. NEWMAN, of San Francisco, Calif., writing us March 20, said :

"All here are tickled that 'the drouth is now broken. The whole State is drenched, but in the southern part it is said to be too late to give crops. I hope not. This is a peculiar country, and everything depends upon rain at the right time, else all is lost."

"GOOD THINGS FROM OTHER JOURNALS" is a new department in the Bee-Keepers' Review, to be selected by Dr. A. B. Mason. In this department he selects the items especially to be commended, commenting upon them, and in some cases emphasizing them by giving some of his own experience. In the March Review he makes his introductory bow, and gives place to two items from the American Bee Journal, and one from Gleanings. The first item is that given by Mr. Doolittle on the advantages of using frames of regular size for nuclei; the second by the same man is the plan of preventing the robbing of nuclei (if the reader is not thoroly familiar with it he should at once turn back to page 2 of this journal); and the third relates to the resources of Cuba as related by Mr. Somerford, and it makes the Doctor's head swim to think what big money may be made there by enterprising Yankees.

BRASILIANISCHE BIENENPFLEGE is the name of a monthly bee-journal started in Brazil about a year ago. It is printed in the German language, and edited by Emil Schenk, Curitiba, State of Parana, Brazil, South America. Its editor requests us to mention his paper in our columns. While doing this, we might add that it is printed monthly, contains 24 pages, at \$1.25 a year, illustrating mostly the Brazilian method of bee-keeping, their different kinds of common and stingless bees, and other things of interest. The principal contributor on our American system of bee-keeping appears to be L. Kreutzinger, 2872 N. Hermitage Ave., of this city, who is also authorized, as seen from the pages of said journal, to receive subscriptions for that paper from the German-speaking bee-keepers of this country.

MR. F. B. MILLS, of Rose Hill, N. Y., is an enterprising seedsman. The 10-cent due bill that he furnishes to all who write him for a catalog, is proving a very liberal offer, and our readers need have no fears that they will be unfairly dealt with. Better send at once for catalog and get a due bill, which will help pay for your season's seeds. The object in making this liberal offer is to induce those not acquainted with Mr. Mills to try his seeds for this season. Mr. Mills feels confident that one season's trial will make a permanent customer. Please mention the Bee Journal when writing to Mr. Mills or any other of our advertisers.

THE INLAND PRINTER, of Chicago, in its department of newspaper criticism, had this to say in its March issue, in reference to the American Bee Journal :

"A careful inspection of the Journal reveals no flaws in its typographical appearance. A most careful attention to every detail is evident."

Coming as this testimonial does, from the leading printer's journal of the United States, we appreciate it very highly, and will strive to merit the good opinion expresst.

WHAT TO EAT—the appetizing name of a monthly magazine publisht in Minneapolis—devoted a whole page of its March issue to "Honey as Food," copying, upon our suggestion, several pages from "York's Honey Almanac." We wish that more magazines would thus publish the truth about honey. It's a good thing to keep going. Every bee-keeper should get his local newspaper to make extracts from our almanac. It will help their readers, as well as those who have honey to dispose of.

PRES. WHITCOMB, of the United States Bee-Keepers' Association, is called "The king-bee man of Nebraska." At least that is what the Herald, of Chester, Nebr., called him, when giving over a column of an address he delivered on "The Organization of the Honey-Bee and the Relation of Insects to Flowers." We shall expect to hear something of the eloquence of "King-Bee Whitcomb" at the Philadelphia convention, next September. He'd better lay in a good supply before starting.

MR. AUG. J. MUTH, son of the late Chas. F. Muth, of Cincinnati, Ohio, died March 4th. The son had just arranged to continue his father's bee-supply and seed business, but was called away. This leaves the business for sale, as will be noticed by an advertisement on another page. We think it would be a fine opening for some young man with capital and enterprise.

Old Foundation is Still Good, according to G. M. Doolittle, in *Gleanings*. Feb. 15 he was putting foundation about a year old in sections, and foundation purchased in 1896 in brood-frames.

A Handy Way to Carry Bees, according to the editor of the *Bee-Keepers' Review*, is to pick up the hive and carry it on the shoulder. This does not apply to hives with loose-hanging frames, and hardly to very large hives. It is especially appropriate for Heddon hives.

Taking Bees Out of the Cellar was discussed at the Brantford convention, the prevailing opinion being that they should be put out early—in March or April; some preferring to take out all at once, others by installments. No uniformity of opinion as to whether they should be put on the old stands.—*Canadian Bee Journal*.

Is Extra Prolificness Desirable?—To the argument that users of small hives never really know how prolific their queens would be if given room, Editor Hutchinson, in the *Bee-Keepers' Review*, replies that there is no object in having one queen lay so much; the object being a big lot of bees whether from 80 or 100 queens.

To Preserve Fruits in Wax.—Take the fruit a little before it reaches maturity, being careful that it is in every way without bruise or blemish, and retaining the stem. Holding the fruit by the stem, dip it in melted beeswax that is not too hot, and gently remove it. It will have a thin envelop of wax, and if put in a cool, airy place, will keep nicely for several months.—Prak. Wegweiser.

Wax from Old Combs with Solar Extractor.—Editor Hutchinson having said that when old combs are put in the solar extractor, $\frac{1}{2}$ or $\frac{2}{3}$ of the wax is lost, O. O. Poppleton makes, in the *Bee-Keepers' Review*, the following report: Number of combs rendered, 32; amount of purified wax, 9 pounds; amount of residue, 3 pounds, 15 $\frac{1}{2}$ ounces. He thinks that not a third of the residue was wax.

The Morton Swarming-Pole is figured and described in *Gleanings*, it being the invention of the late Miles Morton. A square pole slides inside a hollow pole, or long box, 2 inches square and 12 feet long. It is an extension affair, a pull upon a rope sliding the inside pole up, so that it may be made to reach a swarm 30 feet high while the operator stands on the ground. If the swarm is higher than 30 feet, the pole is still a help, for one need not climb so high with the pole as without it.

Varieties in Nectar-Secretion.—F. Greiner gives some interesting points in regard to this in the *American Bee-Keeper*. Cherry-trees are valuable for honey in Virginia, and almost worthless in Western New York. Apple is better for honey North and South. The great honey-plant, white clover, in his locality yields only enough for brood-rearing three years out of four. O. L. Hershiser exhibited at a convention some white honey which he felt sure was golden-rod, while golden-rod is almost universally considered amber.

Scolding Bees.—Rambler wants to know why it is that when you are at work in the apiary, two or three bees will follow and scold you when it might be a thousand as well. He says if you knock the scolders down, in five minutes another two or three will take their places. Dr. Miller says the rule with him is that when the two to six scolders are batted down, peace prevails. Editor Root says he finds it sometimes one way and sometimes the other, but he thinks it is good practice to knock down the scolders.

Do Large Hives Have Larger Colonies in Spring?—A question of fact enters into the large-small-hive discussion. The advocates of large hives say they will have a stronger population in spring. W. Z. Hutchinson, editor of the *Bee-*

Keepers' Review, says this is an unwarranted assumption. For several years he had three sizes of hives—8-frame, 10-frame and 11-frame—and he still uses 8's and 10's, and he is sure that the most populous colonies are not always found in the larger hives. Large-hive men want a hive large enough to fully accommodate the most prolific queen at any time, while he wants a hive large enough to accommodate the average queen. If there is more room in the brood-chamber than the queen will occupy, white honey goes in there that should have gone into the super.

What Darkens Honey-Combs is a matter that has been pretty thoroughly discussed in *Gleanings*. Aside from some cases of darkening by pollen, J. E. Crane thinks the first brown color given to the combs is from the cocoon. Dr. Miller thinks Cheshire is right in saying that the darkening is due to the residua of the bowels of the larva being plastered outside the exuvium, within the cell-wall. But he thinks white sections in the super, if left on long enough, are darkened by dark material being carried up from below. Both are agreed that the feet of the bees have nothing to do with darkening.

The Curative Properties of Honey are strongly lauded in an item in *Centralblatt*. A lad had his knee badly injured by falling on a hard object, and the physician said it was a serious matter of several weeks. In spite of the different remedies applied there seemed no diminution of the pain and inflammation. The father then resorted to the use of honey, wrapping well the injured part with it. Within a quarter of an hour after the application the lad fell asleep, peacefully sleeping several hours, and on awakening declared the pain was all gone. The remedy was continued, and in 10 days he was about as usual.

Selling Sections by Weight and by the Piece.—In reply to the proposition of J. E. Crane, that sections should be sold by the piece and not by weight, R. A. Burnett, the prominent honey commission merchant in Chicago, says there are many difficulties and many things to be considered. He says the demand for 14-ounce sections comes from those dealers who want to undersell their neighbors, and yet equal or excel them in profit. He concludes by saying: "We have thought very much on this question, and can never get away from the conviction that the only fair and accurate way is to buy and sell honey by weight."—*Bee-Keepers' Review*.

Equalizing Colonies Before the Honey-Flow was discussed at the Brantford convention, some favoring, some opposing, according to the report in the *Canadian Bee Journal*. The chairman, Jacob Alpaugh, said:

"I have done some equalizing; that was in times when I did not have as many bees as later on. I believe you can do it to advantage, but you need to be careful; it is worse than spreading brood—to take from one hive and give to another. Go to your strong hive, take out a frame of hatching brood, take it to a weak colony and replace it for a frame that is just full of eggs, and take that back to the strong colony. You will find them both strong, afterwards, and no loss of brood; the same bees are there to cover the same amount of frames."

Is Swarming Contagious?—A good deal of testimony, one time and another, seems to show that it is, and that the excitement of a swarming colony may induce others to issue that would not at least have issued so soon. F. E. Brown reports a case in which he had 18 swarms in the air at one time, all settling in one bunch. One swarm after another settled on a slender cedar-tree 10 feet high, which accommodably bent to the ground. Then the bees were put into hives and set on stands, many of them swarming out again as fast as they were hived. This was kept up a good part of the day. The middle of the afternoon the operators gave it up as a bad job and sat down to watch what the bees would do. At 4 o'clock they arose in a body, but instead of sailing off lit on another tree. The air was black with the roaring mass, and bees in hives apparently quiet left brood and honey and joined the saturnalia. As the day waned the bees began going back to their hives, and when account of stock was taken there were 18 new swarms. The next day was a repetition, the 18 swarms being as frantic as ever, and all that spring on heavy swarm days the bees from new swarms would desert, leaving brood and honey.—*Gleanings*.

Root's Column

40 percent discount on 1898 Fences

—AND—

10 percent discount on Supers
packet with 1898 fences

IN ORDER to clean out from our branches all that remain of last year's stock of Fences, and Supers packet with them, we offer them while they last at a sufficient reduction to make them move. Last year's fences, though not perfect, can be used by those who prefer cheapness to perfection. The cleats are 1/2-inch wide, where we now make them 5-16 and 12 to 2 inches thick, while we now make them 13 to 2 inches. Slats are a little closer together in some cases than this year. These changes are so slight as to be scarcely appreciable in results. There is some stock at all of the addresses given below, which we offer, while it lasts, as follows:

| | |
|----------------------------|-----------------------------|
| '98 P fences, 60c per 100, | \$5.40 per 1000 |
| '98 I " 75c " | 6.50 " |
| '98 S " 70c " | 6.00 " |
| '98 2P or 2I-8 supers, | \$1.10 for 5; \$2.20 for 10 |
| '98 4P or 4I-8 " | 1.80 for 5; 3.60 for 10 |
| '98 AD52P or I-8 hive, | 5.00 for 5; 9.00 for 10 |
| '98 AD64P or I-8 hive, | 6.00 for 5; 11.00 for 10 |

Usual extras for 10-frame Supers and Hives.

In the multitude of counsellors there is safety.—Prov. II 14.

What About the "Golden" Comb-Honey Management?

[These questions were sent out and answered before the recent series of articles by Mr. Golden were published. EDITOR.]

Query No. Referring to Mr. Golden's comb-honey articles, on pages 481 and 883 1896, and Mr. Hartzell's on page 742 1897, I would ask you to state briefly—

1. Would you adopt it in preference to other methods?
2. Do you consider it worthy of fuller trial?—S. D.

E. S. Lovesy—1 and 2. Yes.

D. W. Heise 1 and 2. I don't know.
Rev. M. Mahin 1. I would not. 2. It may be.

A. F. Brown 1. No, not entirely. 2. In a measure.

Mrs. L. Harrison—No time to look up references.

Dr. J. P. H. Brown—1 and 2. I have never tried them.

J. M. Hambaugh—1. I really don't know. 2. I can't say.

E. France—I cannot say, as I have not your references at hand.

Dr. C. C. Miller—1. I have not adopted it. 2. I have not tried it.

Emerson T. Abbott—My advice is, let the other fellow do the experimenting.

O. O. Poppleton—I know too little about comb honey to answer these questions.

J. A. Green—1 and 2. The method looks plausible to me, and I consider it worthy of a trial.

S. T. Pettit—1. I never read it in full, so I am not in a position to judge. 2. I don't know.

R. L. Taylor—1. No. 2. I see nothing to recommend in it. Mr. Golden practically acknowledges it a failure on page 742 (1897).

Jas. A. Stone—1. The methods referred to looks reasonable, tho I cannot speak of them from experience. 2. I don't like to recommend what I have not tried.

C. H. Dibbern—1. I would stick to such methods as have been most successful with me until experiments with other methods have convinced me that they are better. 2. Yes.

P. H. Elwood—1. Not yet; not having tried it I am not qualified to say much about it. 2. I have not tried it because I thought a fine quality of comb honey could not be produced by that method.

G. M. Doolittle—Nearly all have methods of their own which they consider just a little better than those adopted by others. Golden's methods are good, but mine are just a little better. "Do you see?"

R. C. Aikin—1. No. 2. Probably in a limited way. Let Messrs. Golden and Hartzell get in their 1898 reports.

FROM MAKER TO USER AT WHOLESALE PRICES

When Mr. Golden gets past the first flush of enthusiasm to where he can see clearly, he will modify some. I cannot here tell why.

J. E. Pond 1 and 2. Mr. Golden's method is not mine. To my mind it presents no features that are of especial value. Tests may prove it of great value; let those who have time and faith make the tests.

G. W. Demaree- 1. Without expressing an opinion as to the practicability of any new or so-called new arrangement in honey-producing, I would be mighty slow to upset a well-tried system for something new. 2. While I have lost time and some money in making trials, I am still liberal along that line.

Carbolic Acid Instead of Smoke.

I notice some mention of using carbolic acid in place of smoke. Now it seems to me that bee-keepers have enough to contend with without adding carbolic acid to the list, as everybody knows it is very poisonous. Suppose in handling the acid some of it is spilt on the face of section honey. Would it be safe to eat? And if it becomes generally known, will it not be a hindrance to the sale of honey? I think it will in this market.

There are a good many bees kept in this county, but very few in frame hives. I have 18 colonies in 8-frame dovetail hives, part Italians and part blacks.

I ordered one dozen queens last spring, and introduced seven in one apiary without a single loss; five in another apiary with the loss of two.

My 18 colonies are wintering well on the summer stands, with the exception of some of them being light in stores; but I have frames of sealed honey to give them the first warm day. J. R. ADEN.

Henry Co., Tenn., Feb. 18.

All Right, Let Young America Invent

MR. EDITOR:—It seems to me that you are very wrong in what you say in your editorial headed "Inventive Beginners," on page 24. You credit the trash in the way of poor hives which have been tried and cast aside to bee-keepers, and especially to young bee-keepers, when the real fact is that the hives of the Patent Office can mostly be traced to men who never handled bees but were good carpenters and cabinet-makers—men well used to handling tools but not conversant as to the wants of bees. As witness, the hives were mostly built with drawers like a bureau, or were like a kitchen-safe. These hives workt very well for one or two seasons, but the bees glued up the drawers and the hives became worthless to the apiarist.

But there is plenty of room for improvement in the hives now in use in this country, tho our supply dealers are making a very fair hive. You see there is a lot of new bee keepers coming on every year, and there will always be a good demand for the factory-made hive. But don't you try to stop the inventive genius of Young America in the making of hives, to please any gentleman of the Old World. If our Langstroth had confined himself to the systems of our masters we should have been very far behind to-day in the matter of hives, as well as in every other branch of apicultural knowledge. Our Millers, Dadants, Poo-littles, Aikins, Aspinwalls, Taylors, and an array of others, ought to have sat down and waited for the masters of the Old

Address, **GEORGE W. YORK & COMPANY,** 118 Michigan St., Chicago, Ill.

World to get through with the straw-skep and the toy hive!

We are very far still from perfection in the matter of bee-hives, and I hope some young apiarist will yet come to the front with the very hive we are all looking for. Our varying climate and ever-changing seasons make it hard to get up a hive to suit the whole country, but let the young and enthusiastic bee-keepers keep on trying. Don't stop them to please any man from across the seas. I know that we owe a good deal to them—to Cowan, Cheshire, Huber, Dzierzoo, Swammerdam, Mehring, Bertrand, Hruschka, and others, but not in the way of hives. So let Young America have the tools and let him use them, please. Republic Co., Kan. WM. EAGERTY.

Season of 1898, Tall Sections. Etc.

We did not have an extra season last year, but did tolerably well. I got 2,500 pounds of honey from 48 colonies, and the increase of colonies a little more than covered the loss. The season was very wet and bees could not do much, but late in the season we got some real nice honey from golden-rod and wild-aster, and the bees filled their brood-chamber so that we did not feed any for winter-stores.

Most of the honey we got in the early season was mixt with honey-dew, and was not very nice. I sold most of my honey for 12 1/2 cents none for less than 10 cents. The honey that was put in the plain sections with fences was real nice, particularly the tall sections, 3' x 5 1/2'. I like them better than anything I have used for some time, and I expect to use nothing else but plain sections with fences during the coming season.

I was quite amused when I read, on pages 94 and 95, Mr. M. Fouts' article condemning the Danz. hive, tall sections, and the Golden method. I beg leave to differ from Mr. F. in regard to the Danz. hive and tall sections. I have but one of the Danz. hives, but I like it very much; it is true they are a little more difficult to manipulate, but I consider the extra surplus we get more than balances the extra trouble; and the tall sections—well, they just can't be beat. I have no trouble to get bees to work in them; in fact, when fences are used, I believe they will occupy them sooner than they will with the old-time scalloped sections; and, besides, they look so nice, are better filled, and bring a better price; at least that has been my experience.

As regards the Golden method, I have not tried it, but I expect to do so during the coming season, if I live, and I will then tell after the season is over how I like it. I shall not condemn it until Dr. Miller and Mr. Doc little say it is no good. Rockbridge Co., Va. P. I. HUFFMAN.

An Old Lady's Bee-Experience.

I read an article in Green's Fruit-Grower on how to unite weak colonies. It was to make a small hole in a paper and put on one hive, and set the other on top and close the entrances of the top one and the bees would go down a few at a time. But it would not work for me. In an hour's time there were lots of dead bees on the paper. I had smasht both and taken out the empty frames of both, and caged the one by the side of the other one, bottom-board and all. So when I found that plan would not work, I set it off on the bottom-board, then uncovered both and puffed some smoke on both. Each one had four full frames or combs, so I lifted the four out of the one I had on top and put them in the other hive, bees and all, so that made eight full frames. Then I puffed some smoke on them and put on the canvas and cover and left them. I did not see any more dead bees.

Each one for a couple of days stayed on its own frames, then they got together in the middle and seemed to do all right. It was the last of September or the first of October, I don't remember which, when I examined them, and they were all right and seemed to be strong. When I last saw one on the porch I thought that I that saw

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

Prices of Alfalfa Honey.

A sample by mail, 5 cents, to pay for package and postage. By freight one 60-pound can, 8 cents a pound; two cans, 7 1/2 cents per pound; four or more cans, 7 cents per pound. Cash must accompany each order. We guarantee purity.

GEORGE W. YORK & CO., 115 Michigan St. Chicago, Ill.

Page & Lyon Mfg. Co.

NEW LONDON, WIS.

Operates two Sawmills that cut, annually, eight million feet of lumber, thus securing the best lumber at the lowest price for the manufacture of Bee-Keepers' Supplies.

They have also one of the LARGEST FACTORIES and the latest and most improved machinery for the manufacture of Bee-Hives, Sections, &c., that there is in the State. The material is cut from patterns, by machinery, and is absolutely accurate. For Sections, the clearest and whitest Basswood is used, and they are polished on both sides. Nearness to Pine and Basswood forests, and possession of mills and factory equip with best machinery, all combine to enable this firm to furnish the BEST GOODS AT THE LOWEST PRICES.

Send for Circular and see the prices on a full line of Supplies.

Carloads of Bee-Hives.....

AUGUST WEISS, Hortonville, Wis.

Doolittle's Book Free!

Every Bee-Keeper should have

SCIENTIFIC QUEEN-REARING.

YOU CERTAINLY will have it if you desire to know how to have queens fertilized in upper stories while the old queen is still laying below; how you may safely introduce any queen at any time of the year when bees can fly; all about the different races of bees; all about shipping

queens, queen-cages, candy for queen-cages, etc.; all about forming nuclei, multiplying or uniting bees, or weak colonies, etc.; or, in fact, everything about the queen-business which you may want to know. The price of the book is \$1.00, being bound in cloth, gold-lettered.

We want 1,000 New Subscribers

Between Now and June 1,

And we would like to have our regular subscribers help us in this work. In order that all who may want a copy of Doolittle's "SCIENTIFIC QUEEN-REARING" may earn it very easily, and at the same time aid in swelling the Bee Journal's list of subscribers, we wish to make the following **Liberal Offers**—only to our present subscribers:

Offer No. 1. We mail the book for \$1.00, or Club it with the Bee Journal for one year—both for \$1.70.

Offer No. 2. Send us **Three New Subscribers** to the Bee Journal for the balance of the year, at **60 cents each**, and we will mail you a copy of the book free as a premium.

Offer No. 3. Or, send us **two new subscribers** to the Bee Journal for the balance of this year at **60 cents each**, and 40 cents additional making \$1.60 in all, and we will mail you the book.

Offer No. 4. Or, send us **one new subscriber** to the Bee Journal for the balance of this year at **60 cents**, and 65 cents additional making \$1.25 in all, and we will mail you the book.

Now, the sooner the new names are sent in the more copies of the Bee Journal they will get for their 60 cents, and if sent before April 1, each will be certain of getting the Bee Journal for **nine months**, or about 40 copies.

Remember, that only our present subscribers can take advantage of the last three offers above.

Now, let everybody go to work, and help roll up the 1,000 new subscribers.

Address,

GEORGE W. YORK & CO.
118 Mich. St., Chicago, Ill.

might be dead, but it was not. I also united two in that way for a friend that got two colonies in the spring from me, but I have not seen her since I have examined mine. I will after this treat all weak colonies that way.

I find the American Bee Journal a very useful help to anyone that has bees. I would not like to be without it now, as I know how helpful it has been already to me. I have been in the bee-business three years, bought one colony and took two on shares a year; now I have 11 and sold 4. I have lost one during this last cold spell. I had it on the porch sheltered from the north and west. I put it there because I thought it would need attention. The 11 outside I examined yesterday, and they seem to be in good condition, so I think they will come out all right.

I like to work with the bees. I have a large box put over a part of the hive, and lay stuff in between the hive and box, a cover over it, and a good cushion in the top part of the hive. Some with fodder around all but the entrance, and tied over the top. All seemed to be doing well. As I don't have the money to buy hives, I made all I have used. I make them in the winter and paint them, and have them ready when I need them. For the frames I get strips sawed and planed at the mill and nail them myself. I space them by driving a small nail in the edge of the frame near each end, the first one on each side to go against the hive, and on the other side for the next one to go against; and the same with the rest on the one side, so they will stay the proper distance.

I buy dry-good boxes and rip them up in the proper depth for the hive, then saw them the right length, then nail them together. I do not spare nails where they will do any good, so they are strong and good. What isn't thick enough for bodies I make tops and bottom-boards, and what won't do for them, I make frames to set the hives on. I don't have them on benches, so I use the lumber up close. The boxes are planed and grooved so a seam doesn't hurt them. If there is a nail-hole, or anything, I putty it before I paint it. For one box I paid 25 cents, and made what I would have had to pay \$1.50 for, if I had bought the bodies. I ript the boxes and sawed them up, and made six bodies ready to paint in one day. Don't you think it pretty good for a woman in her 70th year? The sawing and nailing was good exercise during that cold weather we have had. I have made 26 bodies, tops for all, a lot of bottom-boards, and a lot of frames to set the hives on; and almost all are painted, and all the pound boxes ready that I will need, and other things ready, all this winter. So I will not have anything that way to do when I need them. I credit the bees for all I sell from them, and charge them with all I buy for them. I have on hand more than I will need all summer, except some more of the foundation for the bodies. All I have on hand, and all I have used, don't come half way to what I made from them last season. MRS. SARAH I. GRIFFITH, Cumberland Co., N. J., Feb. 27.

Successful Wintering of Bees.

I feel as if I would like to "speak in meeting," as I see others are giving their testimony on the line of out-door wintering of bees. I have had but three years' experience in this direction, but they have proven successful. The hives I use are the Bay State or Alley, and Dr. Tinker's pattern. They are mostly of the Bay State make, 8 frames with closed ends.

In preparing for winter I put the hives in rows running east and west, fronting to the south. I put down on the ground 2x4 scantling, raising them an inch or two higher. On these I put a board or two running lengthwise; this constitutes the platform on which the hives are to rest. I commence at the east end of this platform, storing away my bees for winter. I leave a space between each hive, from 4 to 6 inches. After all are thus placed, I lift the covers and pack with 2 inches of straw all

SWEET CLOVER

And Several Other Clover Seeds.

We have made arrangements so that we can furnish Seed of several of the Clovers by freight or express, at the following prices, cash with the order:

| | | | | |
|----------------------|-----|--------|--------|--------|

around the brood-chamber, and put 4 inches of straw on top, and then put on the covers. Then I pack straw in between each hive, taking pains to pack it solid. Then I bank the hives on the north side with straw 10 or 12 inches deep, putting some pieces of boards or sticks to hold it down. I then put about 4 or 6 inches of straw on top and cover this with boards, leaving the front of the hives exposed.

This winter, a part of the time, the hives were invisible; snow had drifted and completely hid them. March 2d I shoveled away the snow, and as I cleared the snow from the entrance there came the old familiar buzz; 20 colonies thus responded all in the row. I thought that pretty good for this frozen region, where the mercury went down to 52 degrees below zero.

My bees have had two or three flights during the winter. Thus I have wintered my bees successfully out-doors for three winters. I think they have come out fully

as well in the spring, if not better, than those I wintered in the cellar. I think that bees generally are wintering well in this locality. L. ALLEN.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, March 21.—Fancy white, 13c; No. 1, 11@12c; ambers, 9@10c; dark, 7@8c. Extracted, white clover, 8c; other kinds, 7c; amber and dark, 5@6c. Beeswax, 27@28c.

There is no change of consequence since our last quotations. Stocks of the best grades of white comb are being reduced, and receipts are light, with some accumulation of the off grades, there being additions to those grades from time to time. R. A. BURNETT & CO.

DETROIT, March 9.—Fancy white comb scarce and higher and we now quote it 13@14c; No. 1, 12@13c; fancy dark and amber, 10@11c. There is considerable poor honey in the commission houses which is offered at 8@9c. Extracted, white, 6 1/2@7c; dark, 5@6c. Beeswax, 25@26 1/2c. M. H. HUNT.

KANSAS CITY, March 10.—Fancy white comb, 13c; No. 1, 12c; amber, 11c; dark, 10c. Extracted white, 6c; amber, 5c; dark, 4 1/2c. Beeswax, 25c. C. C. CLEMONS & CO.

NEW YORK, March 8.—Fancy white, 12c; No. 1 white, 10@11c; amber, 9c; buckwheat and dark, 6@7c. Comb honey is pretty well cleaned up now and we expect to dispose of the balance of our stock during this month. Excepting California there is not much stock of extracted on our market. Demand is fair at unchanged quotations. Beeswax, 27@28c. HILDRETH BROS. & SEGELKEN.

SAN FRANCISCO, March 15.—White comb, 11@10 1/2c; amber, 7 1/2@9c. Extracted, white, 7 1/2@7 1/2c; light amber, 6 1/2@7c. Beeswax, 24@26c.

Present slim stocks admit of only a light jobbing business being transacted, with values much the same as previously noted. The coming crop is likely to be small. The bees are now being fed in a large portion of Southern California, and many are reported to have already died.

BOSTON, March 10.—The demand for comb honey is very light, with full stock on hand. We quote our market: Fancy white, 13@14c; No. 1, 12c; No. 1, 11@12c; light amber, 9@10c. No demand for buckwheat. Extracted, white Northern stock, 7@8c. Beeswax quiet at 27@28c. BLAKE, SCOTT & LEE.

OMAHA, March 13.—The stock of comb honey in this market is very light. There are not over 300 cases of all grades in first hands. Demand continues fairly active. Fancy white quotable at 13c; choice, 12c; No. 1 amber, 11c. Extracted well cleaned up. PEYCKE BROS.

BUFFALO, March 10.—There is only very little dark poor honey in our market, which is selling at mostly 8 cents. Some strictly fancy white comb honey would bring about 12 cents. Little, if any, here. No extracted to mention. Fancy pure beeswax, 30c. BATTERSON & CO.

CLEVELAND, March 9.—Fancy white, 13@14c; No. 1 white, 12@13c; A No. 1 amber, 10@11c; No. 2 amber, 9@10c; buckwheat, 8c. Extracted, white, 7c; amber, 6c; buckwheat, 5c. A. B. WILLIAMS & CO.

MILWAUKEE, March 2.—Fancy 1-lb. sections, 13@14c; A No. 1, 12@12 1/2c; No. 1, 11@12c; dark or amber or old, 7@9c. Extracted, in barrels or kegs, white, 7@7 1/2c; dark, 5 1/2@6 1/2c. Beeswax, 25@27c.

Since our last report we have had a very good market for honey, and the demand has been very good for all grades, especially for sections of the best quality, and the demand is good now and small supply. We encourage shipments of best comb. Extracted, fair demand. A. V. BISHOP & CO.

Something About Handling Hoffman Frames.

BY C. DAVENPORT.

LAST season a bee-keeper came from quite a distance to visit me. I was very busy at the time, and upon his departure I told him I was sorry that it was not so I could have given him more time. In reply he said, in effect, that what he had seen me do would be worth a good many dollars to him, as the way I handled Hoffman frames was a revelation to him. Altho sincere in what he said, he of course exaggerated the matter, but as Hoffman frames of late years have probably had a larger sale than all others combined, I am going to say something about handling them, for many who have them consider it a difficult matter to handle them rapidly.

I consider self-spacing frames of some kind (if hives have to be moved to and fro from out-yards) as the only kind worthy of being considered, and even if hives are to remain in one yard permanently, I think self-spacing frames far superior to loose-hanging ones.

I have tried a good many kinds of frames, and frame-spacers, and as I believe I have before said, I prefer the Hoffman frames above all others, and I do not think there is any locality where propolis or bee-glue can be much worse, or more plentiful, than it is here. I prefer, tho, to have both sides of the projections on the end-bars square instead of having a V edge on one side, as this V edge allows and causes much more glue to be put between these end projections. It is claimed that with these V edges there is much less danger of killing bees when the frames are handled rapidly, but any one who has had many of these frames in use for a few years in a locality where propolis is plentiful, knows that in actual practice this is not the case, for glue will be stuck on and around these V edges until they are as wide and fully as apt to catch bees as square edges are; and as for cleaning or keeping the sides of these V edges free from glue, it is entirely impracticable in a large way, but both edges of these end projections must be occasionally cleaned of glue, or in time it will cause them to space so wide that the frames alone will hardly go in a hive, to say nothing about the division-board with a space back of it; and the main advantage of square edges is that they can be more easily and quickly cleaned. In theory it would appear the other way, but in practice it is a hard matter to quickly and effectually clean these V edges without danger of splitting or removing some of the wood. But so far as they, on account of having more glue on them, make it harder to separate the frames, this is a small matter, for no kind or quantity of glue can be put on the end-bar projections that need materially affect the ease or rapidity with which the frames can be

handled, excepting the occasional cleaning of the edges I have mentioned, and if they are handled rightly to start with, this will not be necessary excepting once every few years, for in practice I have failed to see that wide spacing, up to a certain extent, does any harm, but while glue cannot be put on the end-bars so as to cause much inconvenience, here it is sometimes put on and around the ends of the top-bars to such an extent that sometimes in old hives with wood rabbets the ends of the top-bars have broken off before they would loosen. But with hives that have improved tin rabbets, I have never had any trouble in this respect.

The main reason of my success in easily and rapidly handling Hoffman frames is due to a special tool which is made from a piece of steel about 10 inches long, 1½ inches wide, and about ¼ of an inch thick. One end is spread out a trifle and drawn down thin; the other end has a piece on each side cut off in order to bring it down so that it is only

Yucca Plant of California - See page 211.

about ¼ of an inch wide. The point is then bent at a right angle ¼ of an inch from the end. When one opens a hive with this tool in hand it is an easy matter to remove any frame - propolis cannot stand before it.

For instance, if one of the center frames is to be removed, the wide end is inserted between it and the next one, and the rest of the frames including the division-board are shoved over *en masse*; while the hook on one end is

sometimes very convenient for pulling out a division-board or frame, if glue has been allowed to accumulate on the end-bars until there is not much vacant space left in the hive. Its main advantage is that the tool can be hooked or hung on the edge of the hive after the frames have been loosened.

At the time the visitor I mentioned was here, I was making artificial swarms from some hives containing Hoffman frames, and some from hives with loose-hanging frames. In each instance this necessitated removing all the frames, shaking the bees off, and replacing the frames in the hives from which they were removed. He timed me on a number of hives, and said with Hoffman frames it took me from 1½ to 2 minutes, while with the loose-hanging frames it took from 3 to 4 minutes. This difference was owing mostly to the time it took to space the latter.

With me nails and staples have not proved very satisfactory as spacers; still, there are many who prefer them and object to frames that require the use of a tool to loosen them, but here some kind of a tool is necessary anyway to loosen covers and supers.

Shortly before a swarm is put into a hive containing Hoffman frames, I drive a wedge that fits very tight between the division-board and the side of the hive at each end opposite the end-bars. When this is done, if the frames are made true, it spaces them accurately at the bottom, and by turning the hive bottom side up the frames can be pulled into exact position endwise; and if the wedges are tight enough they will remain so. When this is not done some frames are liable to be a good deal out of position endwise, and after the comb is built they will remain so, and be a continual nuisance, for one end of the frame may be so close to the end of the hive that it will be fastened there, while brace-combs may be built at the other end. As combs are something that, barring accident, will last nearly a lifetime, it pays well to take pains to secure straight combs in frames that are held true in the hive.

Southern Minnesota.

Bee-Keepers' Mistakes in Colorado—Foul Brood.

BY "INSPECTOR."

MY neighbor S. had 3 colonies of bees. He called in early spring at my house to get a few sections. Of course we talkt bees, then I showed him my vat for steaming hives and melting wax.

"I have a few old combs you may have for wax," he said. "Send your boy down and get them."

When the lad returned I saw the evident signs of foul brood, and dispatcht the boy with a note to my neighbor warning him of the danger of letting the bees taste of the honey in the hive from which these combs came. But my caution was too late; the bees had been allowed to clean up the honey daubed on the hive, and the best combs had been placed on the grass near by, so the bees could clean up the honey. Several weeks later the inspector found a large colony foul in this yard.

Near the close of the honey-flow a lady desired her two bee-hives examined. The first hive held a late swarm, but the light it seemed healthy, while 8 or 10 foul-broody combs lay under and against the hive. Ten feet distant stood the parent colony, heavy and populous, with 28 sections well filled with honey, but with the center combs of the brood-nest foul.

My German friend stopt me in the road—"See here, you go *right past* my house, I want you to look at *my* bees." "I will call Saturday."

"All right; I'll be there *sure*," said he.

I came, found L. anxious to learn all about the bees. The first hive was clean, and the brood nice. I said, "Now you see the eggs here, and also the young larvæ so white, and even the empty cells are clean, and shine, all ready for the queen to drop in the eggs."

"And here is the queen, you see."

"Ah, sure! but isn't she a fine one?"

"In moving these combs I will cut out this honey built fast to the side of the hive. Now can you get another frame to put in?"

"O yes, I have some frames of comb upstairs."

This was brought, and on examining found to be foul. We carried it to the window, and the shrunken cells were pointed out, the cappings with the tooth-pick holes and the dried, coffee-colored matter on lower side of the cells were all explained.

"Well," said my friend, "if this is the disease, then

that hive under the willow has it, for I put some of these combs in that hive when I put the swarm in."

"We'll go and see," said I. "You handle the frames and I will use the smoker, while you see if you can find the disease."

Lifting a frame from the center of the brood-nest, he soon discovered the cells containing the foul and ropy matter. "I know what foul brood is," he said; "and now when I understand how to treat the hive, I shall be able to avoid such a state of things hereafter."

Several weeks afterward we met, and when I spoke of the importance of bee-keepers becoming fully informed regarding the danger, he replied, "O you are doing lots of good; I would not take \$25 for what I learned of you."

One yard of about 50 hives was found where a dozen foul hives were emptied and spread over the ground, and thousands of bees were crawling over them. The result of this mistake was the ruin of one-half the bees, and no surplus for that year.

Another yard of 10 or 12 colonies were all diseased but 4. The yard was cleaned, wax melted, and bees that were saved did quite well; but at the end of the season an old hive was found back of the house in the brush; it was dead and foul, and when the cover was lifted several bees flew out.

Large Hives and Small Hives—Swarming.

BY EDWIN BEVINS.

BEFORE proceeding with the subject upon which I intend to write, I wish to say that I approach it with some hesitancy because I presume Mr. Coverdale to be a bee-keeper whose experience antedates mine, and covers a far greater number of colonies than I have yet handled. I will venture, however, to submit a few thoughts suggested by his two articles giving an account of his experience with 10 colonies in 2-story hives, on pages 805 (1898) and 67 (1889.)

What strikes me most forcibly is the *seeming* inadequacy of his motive for making the experiment. I say *seeming* inadequacy because it may be that Mr. Coverdale had motives not avowed, and, again, it may be that I have not a full comprehension of the one avowed. The chief purpose of the experiment, if I gather it rightly, was to learn if the colonies in the double-deckers would swarm as much as colonies in hives of one story. I think he manifests a little surprise that they *did* so swarm, and then he goes on to outline the condition of these colonies, and gives the conditions under which colonies in *any* hive, whether in large or small single-story hives or double-deckers, may be *expected* to swarm. With brood-chambers full of brood and honey, queen-cells present, weather propitious, and a honey-flow on, what is there to look for but swarming, unless the bee-keeper himself intervenes?

It seems that Mr. Coverdale did put on supers at the time the second stories were placed under, but the giving of room above cannot be relied upon to prevent or even retard swarming under all circumstances. With honey enough in the hives to keep brood-rearing going on, and not enough coming in from the fields to start work in the supers, queen-cells may be started, and then it is my experience that swarming preparations will not be abandoned when the flow comes.

My experience with two-story hives is limited, but I have thus far been unable to get much work done in supers placed on top of them.

Contrary to the advice and practice of most bee-keepers, I use hives of six different sizes. The smallest size I use is the 8-frame dovetailed, and I have a larger percent of swarms from these than from any of the larger sizes. The larger the hive the less swarms has been the rule with me. (I will remark here in parenthesis that I do not find any great disadvantage or inconvenience in the use of so many different sizes of hives. My aim is to have enough for a little apiary of each size, and so determine sooner or later which is the best size for me, with reference to both the honey and the wintering problems.)

With regard to swarming, I think the trouble with the small hives is that queen-cells are started before they are started in the larger hives that give more breeding-room for the queen. After these cells are started, room above cuts no figure. The bees will continue their swarming preparations even tho work should be begun in the supers.

In the larger hives queen-cells not being started so soon, the honey-flow may come before any *are* started, then work will be begun above, and perhaps no swarming prep-

arations made. To me, the idea that the size of hive makes no difference with the swarming is a mistaken one. I am willing, however, to say that at almost any stage of the game, when honey is plenty in the blossoms, and weather favorable, the conditions can be changed so as to bring about swarming preparations. Let storage-room above be withheld, and the brood-chamber become congested, and it would not be surprising if some of the bees should get the idea in their heads that they would like to start house-keeping in more roomy quarters.

One remark of Mr. Coverdale's enables me to understand why I lost one of the largest swarms I ever had or saw. It issued from one of my biggest hives, and I reasoned that if I should hive this big swarm in an 8-frame dovetailed hive and put the super right on, I should get a big lot of section honey right away. But the swarm left in a little while after it was hived.

Mr. Coverdale has, it seems, made the discovery which Mr. Hutchinson made years ago, viz.: That bees with young queens are not likely to swarm. Did the behavior of the bees from those 50 queens he introduced without a loss have anything to do with the discovery? I will indulge the hope that Mr. Coverdale will give us the method of introduction in time to be of service the coming season.

Having occupied the stand longer perhaps than is becoming, I will retire and make room for some one possessing that "further knowledge," of which Mr. Coverdale speaks.
Decatur Co., Iowa.

The Yucca Plant of California.

BY W. A. PRYAL.

THE yucca is a rather odd plant; it is also called Spanish bayonet and Christ's candle-stick. It is quite common in the waste places in Southern California, especially in the desert portions. Several varieties are to be found in gardens where it can be protected from severe weather.

The flowers are numerous, drooping and pretty. I have not observed it sufficiently to state whether it is much of a honey-producing plant or not; however, the bees work in-

Yucca Bee Brush

dustriously upon its blossoms. I think it was Mr. William Wallace Bliss, of Los Angeles Co., Calif., who made raids on these plants in the desert places out near the Mojave desert, to obtain the leaves for bee-brushes. Where joined to the trunk these leaves are very fibrous. By cutting them off so as to get four inches of this fiber they may be made into a very soft and serviceable brush for getting bees off combs and other purposes where a small brush is required. The plant is an ornament worthy of any garden.

Alameda Co., Calif.

Teaching Chickens to Eat Drone-Bees.

BY W. W. M'NEAL.

ONCE had a young Brahma rooster whose mind was so great that he appeared never to be happy unless diagnosing a piece of drone-comb containing nice, plump larval drones. The pleasures of the barn-yard, or a stroll in the wood-lot, were of small moment to him after having dined on drones, so I accordingly took him in as a "full member," and called him "Jim."

Now Jim was very young at this time, and would often get lonesome; but to "cluck" to him softly at every such time—which was too frequently the case when I was busily occupied with the combs, for instance, hunting a shy queen—was more than I could stand. To just whistle was so much easier, so I concluded Jim had best learn to catch comfort and consolation from that, and he did. In a very short while he knew the call so well as to come running to me from any part of the bee-yard at the sound of it.

The chicken grew nicely on a diet of drone-bees, and I had much amusement with it. But there came a time one day when I forgot the presence of the pesky rooster, and stood a frame containing a beautiful comb of just-capt worker-brood down on end against the hive. Jim "didn't

do a thing" to that comb, as the saying goes. When I turned to take it up again he was wiping his bill on the grass. He had one square meal on white, juicy bees. I tried hard to forgive poor Jim; but when he shook his short, downy tail and lookt up at me with a sort of sleepy squint in his eye, as if to say, "Much obliged!" I said right out loud that I would break him of eating worker-brood.

This was not difficult to do. As soon as his crop had lost its prominence, I took a couple of imperfect combs, one containing worker-brood almost ready to emerge from the cells; the other large, rounded drone-brood. A few mouth-fuls out of the worker-comb did the work. The difference in size of cell, and the boiled-down taste of the occupants of the smaller cells, soon had him fully in line.

Delicacies in the manner spoken of could not be furnished at all times, and then more mature drones would be substituted. In a little while other chickens began to "catch on," and large numbers of drones were caught at the hive entrance, and upon returning to the hive after a play in the open air. Standing within a few feet of the hive, they would dash up to the entrance, seize a drone, and then hie away to the currant-bushes with a worker-bee on their soft, downy back. This makes the bees very bad about stinging the newly-hatched chicks; so I endeavor to keep these out of the apiary till they are several weeks old.

When a dozen or two of the chicks are in the yard looking for the bee-moths, the unwelcome visitors have to get out of their hiding-places in the grass and go. Chickens should not be allowed in the apiary during cold weather. Their scratching and picking around the entrances to the hives disturbs the bees not a little. Then if the apiary be protected from the wind, and the day clear, yet too cold for bees to fly, chickens are very apt to jump on top of the hives, thereby causing many bees to leave the cluster and perish.

Spring Work in the Apiary.

BY F. A. SNELL.

IF hives, surplus-cases, honey-boxes, and other supplies I have not been secured or made up during winter, this should be done now, and the hives, if procured in the flat, should be put up and painted two coats. I have found pure white lead and oil to be the most satisfactory for this purpose, and the color just what I want.

In putting the hive-bodies and brood-frames together, one should see to it that they are put up square, as should be the surplus-cases and honey-boxes. In fact, do all work to the best of your ability.

The foundation starters or full sheets, as may be preferred, can be put into the brood-frames and honey-boxes if one has a room warm enough at hand in which to do it. To do this work properly, the temperature should be from 80 to 90 degrees, which softens the wax, making it pliable.

All hives and other things likely to be needed should be in readiness before the surplus honey season arrives. The supply should not be scrumpy, but enough for a good season. In case the season is only fair, and the supplies not all needed at the time, the goods will keep with very little loss; but if one is short, in the light of the season, the loss so incurred is often a serious one, and should be avoided, which can only be done by a generous purchase of supplies during spring or earlier. The honey-flow sometimes comes with a rush, as those experienced well know. If one has to send off for supplies, the honey-flow may be over before the goods are received, and the apiarist be left to mourn over the lost opportunity to get a good crop of honey. Bee-keepers err more in not having sufficient supplies at hand than in any other direction.

During March, in our latitude, the bees do not need a great deal of attention, if they had an abundant supply of honey when winter set in. If any are short of stores, the first warm days should be improved in supplying them with food, and for this purpose nothing is as good or as handy as frames of honey, which should be kept in reserve for such purpose. The frames should be the regular size used in the brood-chamber.

During April the warmer weather permits the bees to fly more, and more bloom is present, brood-rearing increases, and the apiarist is rejoiced to hear the more frequent merry hum of his bees. If any colonies are running short of stores, such should be given. Watch should be kept for queenless colonies, and if such are at hand they should either be united with a colony having a queen, or a

queen given, if a good force of bees is present; the latter is often preferable.

Our bees are generally taken from the cellar the early part of this month, the time depending on the season or weather. On removing bees from the cellar it is preferable to give each colony its old stand. All dead bees and litter not cleared from the hives the day put out, which should be a mild one, with the temperature 50 degrees or more, should be removed by their attendant at his earliest opportunity. The hive-entrance should not be large, and depend upon the strength of the colonies; I find from one to three inches about right.

The hives should be as warm as they can well be made to conserve the heat so essential to brood-rearing. No upward ventilation should be allowed, as that would allow the heat to pass off. All these little things should be looked after.

With the advent of May we usually expect quite nice weather for our bees. Fruit-bloom usually comes during this month, and with good weather bees make great progress in brood-rearing; the queen lays at a rapid rate; the circle of brood is spread, and good colonies should have brood in all, or nearly all, the combs in the hive. This month's work in each colony lays the foundation for that colony as a factor in securing the honey harvest from white clover, whether it be good or poor.

At the close of apple bloom we have a slack in the honey-yield. As stores are rapidly used up during heavy breeding, the stores are liable to run short, and the bee-keeper should watch his bees closely at this time, or they may slack up brood-rearing, or even starve, especially if bad weather follows. Brood-rearing should not by any means be allowed to slacken for want of stores. Each colony getting short should be given frames of honey, if at hand, or fed in some way. A very few days' neglect may result in much loss.

Of all times in the season, this is one that the queen should be kept most busy, and the rearing of brood encouraged to the fullest extent possible; and it can only be done when a full supply of food is at hand for the bees' use.

Should any colonies, during this month, be found queenless, they should be duly cared for as stated herein. If any colonies died during winter, the combs and hive should be well cleaned of dead bees, and closed up, if not done earlier.

All these little matters need our attention, and our success depends largely upon our diligence and watchfulness.

Carroll Co., Ill.

Honey Candying or Granulating—Reliquefying.

By H. P. WILSON.

THERE has been a good deal said in the American Bee Journal and in bee-books about candied honey. It is claimed by some old experienced bee-keepers that it is a sign of good, pure honey to candy readily. That may be true, and no doubt it is so far as their experience goes, but my experience doesn't exactly run in that channel. Different climates, and also the source from which the honey is gathered, may make a material difference.

With us the early-gathered honey has never candied in the combs, while that gathered late in the season candies readily. Two years ago I had quite a nice lot of honey, and some of that gathered late in the season was quite solid in the combs in three weeks after being taken from the hive, while all that which was stored early enough to become thoroughly ripened before the cool fall weather commenced, did not granulate at all, altho nearly one-half of it was kept over and sold the next fall and winter.

This past year's honey has not candied any yet, and I account for it from the fact that the honey-flow stopt before the warm weather did. That is, there was sufficient warm weather after the honey was stored to ripen it well. This, however, may not be the sole reason. There may have been a difference in the weather, or in the nectar from which the honey was gathered. The flora, however, was the same each year. I am led to believe from experience that good, well-ripened honey is slow to candy. This may to some extent depend upon the sources from which the honey is gathered.

As to adulterated honey candying, or not candying, I have no experience—in fact, I don't know anything about glucose. There are but two sources from which honey is gathered here to amount to anything—basswood and golden-rod—very little clover of any kind here, and no buckwheat.

I have never extracted any honey. When it candies in the combs I cut up the combs and put them in a pail and set the pail in a pan or basin of water on the stove, dropping in some small sticks from $\frac{1}{8}$ to $\frac{1}{4}$ of an inch thick between the bottom of the pail and the basin. Then I heat the water till it boils, and when the combs are all melted I set the pail away to cool. The beeswax will form a cake on top of the honey, and if there is any pollen it will adhere to the wax, and when taken off the pure honey is left. Any water that might be in the honey is driven off by the heat. I also treat many of the unfinished combs in the same way.

Honey that has once granulated is apt to granulate soon again. Candied honey is melted in the way above stated. There is no danger of the honey being injured by heat. You may boil the water around the pail containing the honey as hard as you can, and the honey won't boil, because it is heavier than water, and won't boil at the same temperature.

I use from two to four quart pails for melting. Honey that has candied in glass-jars can be melted in the same way, only be sure to set the jar in while the water is cool, and let it heat gradually. Don't try to melt candied honey by setting the pail, or jar containing it, back of the stove or near the stove, for if you do you may forget it and scorch the honey on the side next to the stove.

Pembina Co., N. Dak.

The United States Bee-Keepers' Association.

By "KNICKERBOCKER."

THERE is an adage somewhat like this, "If it is a good thing, push it along." Now this is just the thing that bee-keepers in general are not doing. The United States Bee-Keepers' Association should have more names of good bee-keepers upon its roll of membership. "The butchers, the bakers, and the candlestick makers," each has its association, and holds its convention to discuss business affairs for mutual benefit.

The city of Sioux Falls could not accommodate all the members of the butter-maker's convention which was recently held at that place. If there are 300,000 bee-keepers in the United States, we surely ought to have amongst so many several thousand members in the United States Bee-Keepers' Association. If we had the large membership we deserve, we of course would have a large treasury, and with a good financial backing the Association could advertise, and, as Dr. Mason suggested, put an expert salesman on the road, representing it, and help the pursuit in different ways.

I think the present members ought to have more "hustle" about them in getting new members. There is, however, one class of bee-keepers for whom the United States Bee-Keepers' Association has no time to spare. They are those beginners who are always tantalizing the genial Dr. Miller in his "Answers to Questions," by asking questions the answers to which may be found in any book treating on the subject. Every one who wants to keep bees must have a book. The book comes first, the bees second, and the paper third. If one follows this order, and if at the end of a year he is still enthusiastic on the subject, then he is a fit member for our United States Bee-Keepers' Association.

There is another thing that we bee-keepers can do to help each other and the business. Not so much for the bee-papers, but for any periodicals. Good, plain articles showing the healthfulness and cheapness of honey as a regular diet. Good articles are sure to be copied, and in a year the whole country could be wakened up to see the value of honey as a regular food. There would be a tenfold increase in the demand if this were done.

The bee-papers should be the medium for obtaining new members for the United States Bee-Keepers' Association, and the family newspaper the medium for introducing our product.

Turner Co., S. Dak.

[We wish to endorse most fully the suggestions contained in the foregoing. All are excellent. If every one of our readers should read them over about four times, and then try to act on such as they can, we believe the beneficial results all around would be wonderful during the year, just as the writer has said.—EDITOR.]

The Premium offered on page 222 is well worth working for. Look at it.

CONVENTION PROCEEDINGS

Report of the Chicago Bee-Keepers' Convention.

BY A SHORTHAND REPORTER.

[Continued from page 198.]

WHY BETTER QUEEN REARED IN STRONG COLONY?

QUES.—Why is a queen better when reared in a strong colony than in a very small one?

Dr. Miller—When I first commenced keeping bees I learned that you could rear queens in a small nucleus, and I took all the advantage of that I could, and reared queens in a nucleus of one frame, sometimes, and only a few bees. I would not give you a cent a bushel for the kind of queens I reared then. I'll tell you of one I reared, a queen that laid one egg and then died; that one egg was reared in a queen-cell; either the bees or she knew that she was not of much account. I am not sure whether I can fully answer the question. I suppose one of the reasons that a queen is better when reared in a strong colony than in a small one, is that in a strong colony the young larva has all the food it needs, all the heat and care it needs, and in a weak nucleus it may be chilled and fall short of provision. I think the feeding perhaps is the greater part of it.

Mr. Moore—Why is the queen better fed in a strong colony? Do you mean that a little nucleus of three or four thousand bees won't feed one queen?

Dr. Miller—That is not so very little, you know. It does seem that if there are three or four thousand bees, there ought to be enough—the fact is, they don't feed the royal larva as profusely as a strong colony does.

HONEY-DEW IN COOK COUNTY.

QUES.—How many Cook County bee-keepers got honey-dew this season? [4.]

QUES.—How many Cook County bee-keepers here got no honey-dew this season? [10.]

QUES.—How many Cook County bee-keepers got no honey at all. [1.]

Mr. Crego—I had quite a good many sections this year very well filled, in which the honey was a kind of brown color; it was stored about the time that intervened between the storing of the honey-dew and the first of the sweet clover, and I have never been able to settle definitely in my mind what that was; some of it had a few cells of black honey-dew, but more of the sections were all filled by a brownish-colored honey; I would like to know if possible what it is.

Dr. Miller—It is just possible it might have been even then a mixture of honey-dew, with white honey.

Mr. Crego—It was of fairly good flavor—had none of the strong, disagreeable taste of honey-dew.

Dr. Miller—There is a great difference between the taste of honey-dew, and honey which has more or less honey-dew in it. I had some honey this year that had only a little honey-dew in it, and it was really of good flavor. I am not sure but what some would like it better than the pure white honey. Suppose you should put some meat on your plate, and there is no salt on it, and you empty the salt-cellar on your meat, you don't like it, but you do like a little salt. Sometimes you may have a certain kind of honey with a very strong flavor, and it may be honey-dew, and you don't like it, but you like the flavor when there is little of it. I had that kind and I thought it was quite good. Honey-dew varies decidedly: I have had some not fit to eat at all, but what I had this year was of rather good flavor; some of it tastes as much like brown sugar as anything; I am using it now in coffee in preference to sugar.

QUES.—What can honey-dew be used for that is quite strong?

Dr. Miller—I suppose honey-dew, even if it is quite strong, will rear good bees for one thing; and I want to say that you don't use enough honey for rearing bees. In the spring of the year, if you have some honey-dew, you can feed it to the bees; you might just as well have that amount of white honey given back to you; if you don't, there are vacant cells and combs in the hives, and before they put a bit in the supers they are going to fill up their brood-combs, and they will fill up with that white honey.

QUES.—Will they use much of it in the spring?

Dr. Miller—A fair amount. Then this will also make pretty good vinegar. I would count it as profitable as anything, if you have room for it, to have it turned into the bees.

APIS DORSATA AND OTHER BEES.

QUES.—Which is the best bee, the Italian or the Apis dorsata, for the United States?

Dr. Miller—I dare not say. The Apis dorsata is the larger bee, next to the largest; I believe they have a larger size. A good deal has been said about this bee, and a great many bee-keepers are quite anxious that the Government should introduce it into this country.

QUES.—How large is the bee?

Dr. Miller—I think it is something like the size of a small-size bumble-bee. I have heard that it is half as large again as our regular Italian; my impression is that that is not far out of the way. A peculiarity is that the drones and workers are reared in the same size cells, the drones being as small as the workers. Apis dorsata are very large bees, and the thought is if we can get them into this country they will work on red clover; red clover yields lots of honey, but our bees don't get much of it. Get the Apis dorsata here with its long tongue, and it is thought it will work on the red clover. The trouble is Apis dorsata has never been domesticated in its own country. Only a few days ago I saw a letter from a man in the Philippine Islands, and he said where he was they only staid six months in the northern part, and then migrated and staid six months in the southern part. They build a single large comb on a tree. Another man said he had seven large colonies, and the bees left one after another until the queen was left almost alone, and then deserted. A man who wrote about them down in Louisiana, says it is too cold for them there. I am anxious that they should be brought here, but if they should get in this country and be acclimated, I don't see that there would be any gain if they cannot be domesticated; they would simply use some of the nectar that our bees get, and we would be so much worse off.

PROSPECTS IN ILLINOIS FOR 1899.

QUES.—What are the prospects in Illinois for the next summer?

Dr. Miller—In bee-keeping the prospects for next season are always good. I never knew a time yet when bee-keepers, no matter how dire the failure was, did not look forward with the hope that they would have a good season next year. I will say this, that in my locality I never saw white clover more plentiful than it is now, and last year white clover was very plenty. There is this difference between this year and last year; in the fall the clover was burned down to the ground. You would have to get down almost on your hands and knees to find where it was. The roots were there. This year it is green and bright all over the ground, so that if there is any difference there is better prospect this time than last year.

SIZE OF ENTRANCE FOR STRONG COLONY.

QUES.—Are there any objections to allowing strong colonies with plenty of stores a full one-inch opening at the entrance?

Dr. Miller—A strong colony in the honey season will bear more than an inch entrance. I would like if I could have a two-inch entrance to my hives in the honey-season, only that you cannot have too much space under the bottom-bars or they will build down; there is no objection to a strong colony having a one-inch entrance.

LONGEVITY AND PROLIFICNESS.

A Member—The general discussions in the Bee Journal seem to have a tendency to speak of the length of the tongue as being the gauge of capacity, and that with a long tongue bees can get honey from red clover. Would it not be a better idea for the queen-breeders to run on the strength of the bees' wings rather than on the length of the tongue—to rear a bee with stronger wing, so that they won't wear out so easily? If the bee lives twice as long you can cut down your force one-half.

Dr. Miller—Your idea is longevity of the bee; that has been advocated, and with good reason. For instance, here is one colony that will always be full of bees, and will have a big lot of brood; here is another that never has a very large amount of brood, but a good force of workers. The first uses a large portion of its honey in rearing young bees. If you can have longer-lived bees there is a very decided advantage.

QUES.—Is there such a thing as getting too prolific queens?

Dr. Miller—What is the harm?

A Member—I think they would have a natural tendency to swarm late; they will use so much honey for brood.

OPENING IN THE UPPER PART OF THE HIVE.

QUES.—Is there any objection to making an opening in the upper part of the hive to allow the air to circulate thru?

Dr. Miller—Comb or extracted? [ANS.—Both.] I should decidedly object to it for comb honey, but not for extracted. If you make any kind of an opening in the upper part where you are producing comb honey, near that opening the bees will not finish up their combs promptly. For a number of years I followed the lead of Adam Grimm, who was a very successful bee-keeper in Wisconsin. I was at his place one time—it was before the day of sections. He was putting on boxes, and wedged up the cover of his hive, leaving it open perhaps half an inch or more; he said, "I consider that very important." I think he was right; it helpt them to get air, and I think it helps to keep down swarming somewhat; and so, for a number of years after that, I used wide frames after I began to use sections, and the upper story I slid forward, so as to leave one-half inch opening at the back of the hive between the first and second story, that allowed fine ventilation to go thru; but the row of sections next to the opening, if they were sealed up at all, it was a long time after the others were.

[Concluded next week.]

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Climate and Foul Brood—A Difference in Colonies.

On page 181, the question is asked, "Are bees in any particular climate affected by foul brood more than in another?" The answer given is all true enough, but can hardly be called a fair answer to the question. I think bees are more affected in cold than in hot climates. I think in some parts of northern Africa the disease is at present unknown. Whether it is due to the hot climate, the variety of bees found there, or simply to the fact that the disease has not yet been introduced, I don't know.

In reply to the question of J. C. Armstrong, page 188, it may be said that the two colonies mentioned obtained their honey from different sources. One year while all the other colonies were gathering very dark honey, two or three of them stored some beautiful white honey. When the bees of a colony get started on nectar in a given place, they're likely to continue at work in that place so long as the yield is fair.

C. C. MILLER.

Changing to Standard Frames.

I have in excellent condition 8 colonies of very nice bees in 12-frame hives. The frames are just the right size to admit six 4 $\frac{1}{4}$ x 4 $\frac{1}{4}$ sections in the lower story or three of the same in a super. It seems that bee-men in general prefer a 10-frame hive with frames just 4 $\frac{1}{4}$ inches longer than mine, or 17 $\frac{1}{2}$ outside measure, and the same depth of mine, or large enough for the surplus or super frames to accommodate four 4 $\frac{1}{4}$ x 4 $\frac{1}{4}$ sections instead of three, as in mine.

1. Are my hives and frames of a standard size? Are they just as good as the 10-frame hives with longer but same depth frame? I think I see three very good reasons why I should adopt 10-frame hives with 17 $\frac{1}{2}$ frame. In the first place, the bees can more readily reach any frame in the hive from the entrance. Second, in examining say 10 colonies of bees I would save handling 20 extra frames. Third, I would get just as much honey from the super frames of the 10 colonies (if all were full) with 10 frames per hive as I would from my 12-frames with four pounds per super or 40 pounds for the 10 colonies extra.

2. Do you think it best, and would you advise, on beginning (while I've only a few, 8 hives) to adopt the 10-frame, with 17 $\frac{1}{2}$ frame? Are my three reasons valid enough to pay me to make the change in frames, as my old hives are just the size for a 10-frame hive with 17 $\frac{1}{2}$ -inch frame by turning the side to the front and cutting out a rabbit on the (now) side of the same, the frame being all I will have to change? I propose to increase solely by division.

3. If I make this change in frames, can I (successfully) increase that way (by division)? If so, how would you go about it? Would

you put in a division-board crosswise at the back of my short frames? I could put in a long frame by sawing off a part of a division-board and put a narrow piece (which would be 4 $\frac{1}{4}$ wide) from the end of the board sawed off to the back of the hive. Please advise the way you think best for increasing in this exchanging short for long frame case of mine.

ARKANSAS.

ANSWERS.—1. No, you are not using standard goods. Your first objection to your present arrangement is correct, providing your frames run crosswise, instead of having each frame running toward the entrance. Your other objections are correct, and probably sufficient to make a change seem desirable. An additional reason, and one that is of itself enough to decide the change, is the simple fact that what you now have is *not* standard. If at any time you want to buy hives, a standard size will cost less than an odd size. If you should want to sell, the purchaser, if well informed, would be willing to pay more for a standard article. I have been changing my hives and frames for no other reason than that they were not standard size, the difference in size between them and the standard being so little as to make no practical difference in results.

2. You say you intend to increase solely by division. Do you mean that you don't intend to allow your bees to swarm? Not once? You wait and see.

3. I don't believe you'll like the mixt plan you propose. Very likely you will be better suited to put the new hive on the stand of the old, shake off nearly all the bees with the queen into the new hive, and set the old hive on a new stand. To make the bees more satisfied with their new quarters, you might for a day or two put in the new hive one of the short frames, setting it at one side and letting it rest on the bottom. Or you might cut out the comb and fasten it in one of the new frames, leaving it permanently. At the same time it will not be a bad plan for you to have a hive all ready in which to hive that swarm that you don't intend shall issue.

If you don't intend to continue any of the old frames at all, it will be a comparatively easy thing, and the best plan of all, to cut the combs out and transfer them into new frames. This could be done in fruit-bloom, or later, at the time of dividing.

Increase of Colonies Wanted.

I bought three colonies of bees last summer which are now in fine condition. I desire to increase them to as many as I can, and have them strong enough to go into winter quarters safely. What will be my best plan of procedure? I can give foundation, and feed.

UTAH.

ANSWER.—The safest plan is the nucleus method as laid down in your bee-book. That allows to continue increasing gradually as long as the season lasts without the danger of being caught with a large number of weak colonies on hand and none of them strong enough for winter.

Dividing Colonies for Increase.

1. When is the colony in the best condition to divide?
2. How do you divide? (I want to divide but once.) How many frames would you place with the queen part, and where would you place the hive?
3. Will I need to cut out the extra queen-cells from the half that have no queen, and when? Could I use the queen-cells to make up others, and how? Would it pay to buy queens for this half?
4. What condition will the divided colonies need to be in, before I put on the supers for honey?
5. Last year I put on a queen-excluder and kept the queen below. Was that right? Is there any danger of these excluders being too small to let bees through? One bee-man told me his were.
6. In giving a colony frames of honey or foundation, is it best to mix it up in the brood-nest, or put them at one side?
7. What do you think of this way for increase? To confine the queen with a little brood in the bottom of the hive, and let the bees rear a queen-cell in the upper hive, and when capt. move it to a new stand of its own.

MINNESOTA.

ANSWERS.—1. If you can tell when it is in condition to swarm, it will be ready to divide. This will be when it is strong in bees, and honey is beginning to come in plentifully. If you will look in the hive you will find a number of queen-cells started. If white clover is one of your chief honey-plants, a colony will be ready to divide about a week after you see the first clover blossoms, *providing it is strong*. You will be tolerably safe to go by the time you hear of the first swarm anywhere in the neighborhood.

2. There are different ways, and what is best under one set of circumstances may not be best under another. Before thinking of dividing, the most profitable thing you can do is to get a good bee-book and study it thoroly. Then you'll have some basis to work upon and will be ready for emergencies. With no special knowledge, and taking as little work as possible, you may find it your best plan to put in a new hive about one frame less than half the number of frames, taking among them the frame the queen is on, and taking with each frame all the adhering bees, putting this on the old stand and putting the old hive in a new place perhaps ten feet or more away.

3. There will be no need to cut out queen-cells unless the queenless part is pretty strong. If cut out, it should be about nine or ten days after making the division. Yes, if you have read up in your text-book, you can use the cells to good advantage in mak-

ing other divisions, thus saving a good deal of time. One way to do is as follows:

Take from the hive two frames of brood with adhering bees and the queen, put them in an empty hive on a new stand, filling up each hive with empty combs or frames full of foundation. Eight or ten days later let the two hives swap places. Now divide the queenless hive into three or more parts, depending upon its strength, making nuclei out of it, and making sure that each nucleus has one or more queen-cells. To divide up the cells properly, it may be necessary to cut out some of them and nail them on the surface of the brood with a heavy pin or perhaps better a wire nail an inch or more long. Of course the nail must not run through the part of the cell that would interfere with the apartment of the queen. As soon as a queen is found laying in one of these nuclei, you can make it into a full colony. Go to one of the colonies you want to divide, take away from it half its combs with adhering bees, and give to the nucleus. Then brush off the bees from all but two of the remaining combs, and after these combs are brushed add them to the nucleus. Be sure you don't take away the queen. You have now left in the old hive the queen, two combs of brood, and you will fill up with empty combs or frames of foundation. There is also a fair supply of bees there, and this number of bees will be strengthened within the next two days by field-bees returning from the nucleus. This is a good way to double your number of colonies, but of course you'll not get the yield of honey you would if the bees were left without dividing or swarming. You can get along somewhat faster by buying queens. Whether that will pay depends somewhat upon how anxious you are and how plenty money is.

4. They must be strong in bees, and the lower story must have all its frames filled either with brood or honey.

5. Yes, that was all right if working for extracted honey. For comb honey it isn't usually necessary. You will hardly find any of the perforated zinc sold by reputable dealers with perforations so small as to make trouble.

6. You may as well have the frames filled with foundation together.

7. It will work very well if the bees start cells, which they may not always do.

Bees Wintering in a Garret.

I stored my eight colonies in a garret, and the mice have captured one colony already, so I have set about trapping them. The rest seem to be very uneasy, altho the room is as dark as can be, yet the bees keep coming out, and I fear many never return. What causes this uneasiness, and what is the remedy? They are in common hives. How soon will it be safe to place them outdoors? All of these mistakes were the result of not beginning intelligently. NEW YORK.

ANSWER.—Probably no one has succeeded in keeping bees in a garret. Too cold, and in mild weather they can't fly. Set them on the summer stands the first day it comes so they can fly, say 45 degrees or warmer, when the sun is shining.

Keeping Empty Combs for Swarms.

I examined the bees to-day, and found one dead colony. I am sure they had no disease, but they were few in numbers and unable to endure the cold. I am feeding the honey left, back to another colony. The combs contain a few small patches of brood which of course perish with the older bees. Will it be safe to use those combs again next summer? I should like to have one of my early swarms on them, if there is no danger of disease from the pollen and dead larva. If my method of feeding out the honey and saving the combs for a new swarm next summer is not correct, what is a better way to do? MASSACHUSETTS.

ANSWER.—You're all right. But the sooner those combs are put in charge of bees the better. Set the hive containing them under some colony till needed to use for the swarm. That will keep them free from the worms, and the bees will clean them up so they will be sweet and nice for the swarm.

Spring Requeening and Other Questions.

1. How early in the season will it be advisable in this locality to introduce a queen? That is, requeen a colony?

2. How soon after swarming does the young queen usually emerge from the cell?

3. For comb honey, is it best to have a new swarm on full sheets of foundation, or starters?

4. Is it advisable to put in one or two frames of honey with the foundation in an 8-frame hive? I have been advised by old beekeepers to do so.

5. Having no extractor, what is the best way to dispose of honey left by a dead colony? When the swarm has died from diarrhea, should the frames of honey and the hive be fumigated before using again? MAINE.

ANSWERS.—1. Not before fruit-bloom.

2. About a week. If, however, the weather happens to be bad at the time the prime swarm is ready to come off, it may be delayed, and in that case the queen may emerge from her cell in less time than a week after the swarm issues.

3. The majority probably favor full sheets. Some favor hiving

on a limited number of frames (perhaps four or five) having only starters, and some two weeks later filling out with frames filled with foundation.

4. That depends. If honey is coming in at a lively rate it may not be desirable; if a bad spell of weather should occur, it might be of very great advantage to have some honey on hand.

5. They're worth good money to feed to other colonies. There isn't one case in fifty that a colony doesn't use up its honey so as to have some empty combs before fruit-bloom. Take out these empty combs and replace with combs of honey from the colonies that died. No need to fumigate them; if the frames are very badly daubed, scrape them off, the bees will do the rest of the cleaning.

Feeding in the Spring.

In early spring, when bees have a prospect for a flight at least five or six times per week, would you advise feeding them *liquefied* sugar if they are *very* short on stores? If so, in what proportions should the mixture be made? If not, what should be fed? KANSAS.

ANSWER.—If very short of stores, they should certainly be fed, whether they can fly or not, for nothing can be worse than utter starvation. The very best thing is to give them combs of sealed honey. If, however, they can fly five or six times a week, there ought to be no trouble in feeding sugar syrup. When they are flying almost daily it doesn't matter such a great deal as to the proportions of sugar and water, three parts water to five parts sugar making a very good syrup, and those parts may be by weight or by measure.

Brood-Chambers Full of Honey.

I started last spring with six colonies, two of them on 4-frames each and increased to 10 and got 45 pounds of comb honey, which I think is good for this part of the desert.

My bees filled the brood-chamber last fall; I weighed some of them to-day, and they weighed from 50 to 55 pounds each. They are in 8-frame hives, the hives weighing about 25 pounds, thus leaving 25 to 30 pounds of honey, and this is March 10. By April 20 there will be plenty of honey coming in, so they must have a surplus. What is the best to do with it, cut it out and put in frames of foundation, or leave it where it is and let the bees do as they please with it? KANSAS.

ANSWER.—They'll use a lot of honey before they gather any. Better let alone, unless you find the queen crowded for room to lay, then take out a frame.

Spraying Fruit-Trees Rearing Queens.

1. Do the poisons sprayed on fruit-trees have any effect on bees, such as Paris green or London purple? In the spring of 1898 my 54 colonies came out in good shape, and were very strong until after fruit-bloom, then they kept getting weaker, and many of them died. I laid it to the poisons sprayed.

2. Will bees sometimes rear a queen from a worker-egg, or is there no difference in the eggs when first laid? UNION HILL.

ANSWERS.—1. Yes, if trees are sprayed at the time of blooming, the bees that work on them will be poisoned. But nowadays no intelligent fruit-grower sprays trees when in bloom. It can have no effect in preventing the fruit from being wormy, but it does have an injurious effect upon the fruit crop. The number of States is increasing in which it is made a criminal act to spray fruit-trees when in bloom.

2. Yes, bees can rear a queen from an egg laid in a worker-cell, such an egg being the same as one laid in a queen-cell.

One Neighbor Killing Another's Bees.

What can I do to save my bees? My neighbor got some bees last spring and gave them old comb from some dead bees all over his yard. He has his bees under a shed and mine go there and rob his on nice days. He closes his hives in the morning, and kills my bees that go there all day. Can I do anything to stop him, and how? MINN.

ANSWER.—It's just a little doubtful whether you need do anything. It is quite possible that he is killing more of his own bees than of yours. If he closes his hives so your bees cannot enter, your bees will soon give it up as a bad job, and he is killing off a good many of his bees by shutting them in the hives on nice days. Perhaps it might not be a bad plan for you to try a counter attraction for your bees by putting sugar syrup out for them to work on. If you can clearly prove that he is enticing your bees and killing them, you may have recourse in a court of justice. If the trouble becomes very serious you may be sure of assistance by calling on the Bee-Keepers' Union or the Bee-Keepers' Association, providing you are a member, but if you are not already a member it will do no good, for you can't obtain membership if in trouble in advance. You have done a very wise thing if you have secured membership in advance, for no bee-keeper can tell when he may need help, and the trifling amount of a dollar a year is as good as insurance, besides helping your own and the interests of other bee-keepers by putting down adulteration.

United States Bee-Keepers' Association.

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., E. Whitcomb; Vice-Pres., C. A. Hatch; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GEN'L MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

Place and Date of Next Meeting:

Philadelphia, Pa., September 5, 6 and 7, 1899. Every bee-keeper is invited.

VOL. 39.

APRIL 6, 1899.

NO. 14.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

The Sweet Clover Article, by William Stolley, which appeared on page 113 of this journal, is highly spoken of by "Stenog," who conducts "Pickings" in Gleanings. He says:

"It would be a good thing if the whole article could be printed in every agricultural paper in the country."

A correct view; and it may be well to hint that bee-keepers may do something themselves in that direction, wherever they have any influence over agricultural papers. We have some extra copies for those who wish them.

The Honey Market.—J. O. Grimsley, in the Ruralist, thinks the secret of the trouble with the honey market lies in this sentence: "There is not a general demand for honey." As a remedy he suggests a label adopted by the United States Bee-Keepers' Association. He thinks it would make it more popular to call it "Union Label Honey," as that would be very catchy with the members of the many "trades' unions." That seems hardly in accord with the view that made the name change from "Union" to "Association."

Heavy Losses of Bees in certain parts of Michigan are reported in the Grand Rapids Herald of March 20, by Geo. E. Hilton, of Newaygo Co., and the worst month is likely to come yet.

The Worker-Bee—He, She, or It?—Editor Root, of Gleanings, seems to be getting into trouble for becoming a disciple of E. E. Hasty, and calling a worker "he." First, the Hon. Eugene Secor, in a poem occupying half a page, gets in some sharp thrusts. He thinks

"It will never do to have it get out
That FEMALES are WORKERS and bring things about."

With fine sarcasm he closes by saying,

"From this time on, IT ought to be HE
Whenever we speak of the mis-called nenter,
Let's keep the old ruts, and not bend the knee
To modern improvements, tho it does seem cuter.
Young folks are too smart in this land of the free,
And get too far from the time-honored tutor.
Let's teach this doctrine wherever we can:
The old-time angel was ALWAYS A MAN."

Mr. F. Greiner says the functions of a worker are those of a female, for they prepare food for the young, and do all in rearing them except to lay the eggs; speaks of the inconsistencies of language, the Germans calling the queen "he" and a drone "she;" and thinks when the time comes that proper credit shall be given to queen and to worker for their parts performed, it will be "Mrs. Queen and Mrs. Worker."

Apis Dorsata in the Philippines.—Gleanings prints a letter from John C. Uglow, a soldier at Manila, who is also a bee-keeper, and he proposes to send *Apis dorsata* to this country. Editor Root is quite enthusiastic over the matter, and says they will leave no stone unturned to get the big bees, offering \$25 for a live queen. Some may be inclined to inquire whether Mr. Root has changed his mind since asserting that he would not be a party to having the bees here unless under domestication. Perhaps he has that fully in mind, and does not intend they shall be allowed to get loose, for Mr. Brodbeck, in California, is to give the bees a cleansing flight on the way, "but on no account is he to let the queens out."

When to Spray Fruit-Blossoms. Bulletin 142, issued by Cornell University, says:

Never spray a fruit-tree when it is in blossom. You can reach the insect and fungous enemies just as effectively, and in some cases more so, either just before or just after the trees bloom.

Marketing Honey—Practical Suggestions.—We believe Capt. J. E. Hetherington, of New York State, bears the distinction of having produced and shipped to market more tons of comb honey than any other bee-keeper living in the United States to-day. At the Buffalo convention in 1897, he had quite a good deal to say on the line of shipping to market, and in a letter we received from him recently, he refers to the matter again. Here are some of the paragraphs which we take the liberty of reproducing for the benefit of our readers:

All bee-keepers should, I think, have a common interest in influencing producers to send their honey to market (whether in large or small quantities) neat and attractive in appearance, and thereby sustain prices and make our product more pleasing and satisfactory to both dealer and consumer—two very important personages to our success. A clean, neat, attractive case is, to my mind, quite a factor to that end. Where honey is shipped a long distance by rail, cinders and dust work into the car, and after the honey has been handled about twice at its destination, the cases are more or less begrimed, and the "bloom" all gone.

For years I have made a practice of covering my honey, when in transit, with cotton-cloth, to protect it from cinders and dust, which insures a clean, neat appearance when it reaches its destination. The expense is trifling, as the cloth cover is billed with the honey and returned for future use. I brought this before the Buffalo convention as one of the little practical things for bee-keepers to do.

Also, the putting in the bottom of every case a light manilla paper, to hold the drip and prevent the cases from being besmeared by honey, is a good thing.

Value of Bees to Orchards. The great importance of bees in securing better fertilization of fruit-blossoms will become more and more apparent as the producers of fruit learn the facts. We find the following paragraphs in one of our exchanges, which should be past on among all farm papers, as the facts given are of value both to the growers of fruits and the keepers of bees :

Some years ago a great hue and cry was raised in certain sections of the country over the assertion that bees ate holes in the fruit and caused it to decay. Experiments innumerable have been proving the folly of such a statement. In one instance bees were kept in a room where there were dishes of all sorts of fruit, including grapes, pears, peaches and plums. It was noticeable that the fruits that had the skin broken were visited by the bees, but in no case was there any evidence that they troubled the whole fruit.

The value of bees to fruit-growers can scarcely be over-estimated. Some years ago a place was leased to a tenant who kept a few colonies of bees. In one corner of the yard was a very large and thrifty-looking apple-tree that always bore an abundance of blossoms, but no fruit. A number of colonies of bees were placed underneath this tree, and much to the surprise of the owner of the place, the tree was loaded with extremely fine apples—something that had never occurred before within the memory of the man who had owned the place for 25 years. The next season the bees were distributed under trees that had not been in the habit of bearing freely. The most surprising results followed, the trees being full of very fine specimens of fruit. If the blossoms on an apple, plum or pear tree are covered up and the bees are kept away from them until the blossoming season is past, there will be no fruit. This has been tested again and again.

Shape or Condition of Bees.—Dr. Miller's condition these days seems to be that of illness, if we may judge the shape his mind is in from the writing of such letters as the following :

MR. EDITOR:—Recalling that you have been somewhat insistent that when a man said anything about the shape his bees were in he must have reference to their being round or square, or something of the kind, I arise to inquire whether there has lately been a change in a number of cases as to the general contour of bees, or whether the shape of the Editor's mind is different. I ask this because of the frequent mention lately in the "Old Reliable," even in headings, of the shape of bees. If you are in such a condition to enlighten me, I shall be very much obliged.

Anxiously, C. C. MILLER.

Now, look here Doctor, if you want to retain your usual shapely condition, you'd better touch very lightly on such subjects as the above.

You see, the very cold weather this winter has had such an unusual effect on the bees that both their shape and condition have been seriously affected. So, naturally, the shape or condition of the Editor's mind would be different from what it was previous to receiving reports of the unfavorable shapes and conditions the bees are in this spring.

Honey and Bees in Switzerland. In a recent issue of the National Hotel Reporter, we find these paragraphs in reference to bees and honey in Switzerland :

In no country in the world is honey used so generally as in Switzerland. Throuth the country it is an article of daily consumption. At every hotel it is served with unflinching regularity; but the enormous demand has led to adulteration, and the purest honey is rarely found in the hotels. The *ouvrier* class consume it most largely. With his bread and butter, the workman always has honey. "It is healthy," he says truly; "it builds up the body—and it is cheap."

According to the most recent returns, there are about 250,000 colonies of bees in the whole country, or one to every 12 inhabitants; and the yield of a frame-hive colony often reaches 100 pounds of honey per season. The yield from a "skep," however, is much smaller; so that, at an average of 50 pounds per colony, the honey harvest of Switzerland may be taken at 12,000,000 pounds, or some 4 pounds per head of the resident population. These figures do not, of course, represent the actual ratio of consumption,

as account must be taken of the amount consumed by the multitude of tourists.

When it is remembered that the honey is gathered only from the beginning of May until the end of July (that gathered later being required for the bees' own use), it will be seen how unresisting is the energy of the little workers. Nor is this more than a fraction of the harvest which only awaits gathering on the verdant hillsides and rich valleys of the land of Tell.

REV. A. B. METTLER, a Methodist-preacher bee-keeper of Will Co., Ill., called on us while in Chicago last week. His bees seem to be wintering all right.

MR. I. H. PAGE, of Thayer Co., Nebr., wrote us March 27:

"I am more than pleased with the American Bee Journal. I don't know how I have been getting along without it. Long may its banner wave."

MR. W. A. PRYAL, near San Francisco, Calif., writing us March 23, said:

"Regular rain-storm these three days—continous, warm, and heavy; 17 inches for the season. May have flood ere it lets up."

THE INTERSTATE MFG. CO., of Hudson, Wis., is one of the growing bee-supply institutions of that State noted for its many apiarian manufactories. The Interstate is composed of W. H. Putnam, general manager, F. E. Williams, secretary and treasurer, and E. E. Belden, superintendent. They began the season with 30 employees. They are well-equipped for taking care of a large business. Their advertisement is found in every number of the American Bee Journal, just as should be the advertisements of all dealers who want to do business with the bee-keepers of this country. Write to the Interstate Co. for their catalog, not forgetting to say you saw their name in the old American Bee Journal.

THE FARM JOURNAL, mentioned on page 222, is unlike any other paper; for one thing it prints no quack medical advertisements; for another it takes five-year subscriptions and gets the paper to its subscribers the full time if they are anywhere on this planet, even if they move two or three times; if they die their heirs get it. Now we offer to send the 50-cent Farm Journal for the balance of 1899, and all of 1900, 1901, 1902 and 1903, nearly five years, to every advance-paying subscriber, with the Bee Journal one year, all for only \$1.40. Better speak quick, as we have only a limited number of Farm Journals to offer on these terms. See our other offers on page 222. It's a rare opportunity to get \$3.50 worth of the best bee and farm literature for only \$1.50.

MR. L. C. ROOT, son-in-law of the lamented Moses Quinby is living in Connecticut, and has "Mother" Quinby in his family. In a letter dated March 21, Mr. Root says:

"While I do not lose my deep interest in apiculture, I am now managing an almost ideal milk service. With something of a knowledge of my right to make the assertion, I may be pardoned for saying that we have here one of the most correct milk services in all of its details, in the world; and you must know what that means for a manager. It commands my constant supervision from 4 a.m. to 9 p.m. To produce absolutely wholesome milk means much more than is generally understood."

Mr. Root, years ago, revised Quinby's book, "Mysteries of Bee-Keeping Explained," but it seems of late years he has been devoting himself to the milk business in the town where he lives. We like to keep track of the once prominent bee-keepers of the country, and know that tho they may be engaged in other business they have not entirely lost interest in the little busy bee.

For Protection Against Wind and Winter.—Editor Root favors a high board fence. J. E. Crane objects that the wind goes over the top of the fence and swoops down on the hives with increased force. He prefers a picket fence to one of close boards, or else an evergreen hedge so as to slow up the wind. If the wind is stopped too much, it will warm up within the enclosure in early spring, the bees enticed out, never to return.—Gleanings.

Apis Dorsata.—Editor Hill, of the American Bee-Keeper, gives some account of Frank Benton's efforts to secure *Apis dorsata*, and says:

"That no subsequent effort has been made to introduce this bee is a fact not only to be regretted, but calculated to arouse the agriculturists of America to demand governmental aid in testing its qualities, which promise to be of inestimable value to American agriculture."

The Pure Food Bill.—C. Davenport urges that every bee-keeper should write to his member of Congress on a postal something like the following:

"DEAR SIR:—I and others here are much interested in the Pure Food Bill, and we hope you will do what you can to have it past."

Then address with the name followed merely by "Member of Congress, Washington, D. C."—Gleanings.

A Fresh Credit to Sweet Clover is set down in Gleanings. Elias Johnson says it is one of the best *root crops* for cattle. He plowed five acres of sweet clover land, and the cows gathered on it and worked on it for weeks eating sweet clover roots till they had the ground so hard they couldn't get another root. It spoiled the plowing, but almost doubled the milk. He also saw at a county fair towels made of the fiber of sweet clover. They look much like linen, and were very strong.

Black Bees Preferred for Comb Honey.—C. Davenport thinks he can get more white honey in sections with blacks than with Italians. Italians are too much inclined to crowd honey into the brood-chamber when the white flow begins; while blacks will have very little white honey in the brood-chamber at the end of the flow. Blacks cap whiter, and are more tractable when it comes to the matter of mixing and uniting colonies. For extracted honey he prefers Italians, considering the vigorous defense they make against the moth.—Bee-Keepers' Review.

An Interesting Interview with J. E. Crane is given in Gleanings, the interviewer being the Editor. Mr. Crane has about 525 colonies in five apiaries; thinks a smaller number in an apiary would give more honey per colony, but the convenience in handling compensates; produces comb honey and has generally only one helper; averages about ten hours a day of work, and 11 and 12 in the height of the season. When swarming comes, he removes queens from some, cutting out queen-cells, and giving virgin queens after two weeks or more; from others he removes brood-combs, filling up with empty combs or foundation.

Plain Sections are not strongly favored by Editor Holtermann, and he does some vigorous arguing by way of pictures. On one page in the Canadian Bee Journal is given a picture of plain sections copied from the American Bee-Keeper, and on the opposite page is given a picture of "sections with the top and bottom bar only of the section open, with solid separators and section-holders." The latter are beautifully finished out, and are distinctly superior to the former. The advocates of plain sections will, however, be very likely to say that it is hardly fair to take as a representative of plain sections a picture so much inferior to others that have been given of the same class of sections.

Travel-Stain. A second article by J. E. Crane upon this subject appears in Gleanings, in which he maintains the ground that the so-called "travel-stain" is not travel-

stain at all, the feet of the bees having nothing to do with it. He says that the stained combs come in rare cases from pollen carried on the bodies of the bees; in others from propolis mingled with the cappings; but most frequently in the cappings of surplus honey from impure wax carried from the brood-chamber, the impurities being propolis, pollen and cocoons. The original coloring of brood-comb he attributes to the cocoons, in which he is probably in error, as Cheshire says the color comes from the contents of the bowels of the larvæ being plastered on the cell-walls.

Different Locations Require Different Management.—In illustration of this, Adrian Getaz cites in the Bee-Keepers' Review the practice of allowing bees to swarm, hiving on empty frames, and depending on the swarm for surplus. With him the plan would be an utter failure. The swarm would come in mid-May in poplar bloom, and by June 20, when the best flow (the sourwood) comes, nearly all the original bees of the swarm would be dead and few young ones to replace them. The plan will be successful only where two conditions prevail—1st, the flow must be not more than a few weeks; 2nd, the swarming must take place at the beginning of the honey-flow. He thinks these conditions prevail nowhere in the world except in southern Canada and northern United States east of the Rockies.

Conditions in Cuba.—In reply to questions about Cuba, W. W. Somerford says in Gleanings: No trouble from banditti, but plenty from rain, everything being soaked in the rainy season, when for 90 days it never forgets to rain for a single day, and bees may starve if not fed, especially blacks; and no malaria. Wax-moths plenty the year round, but give no great trouble except in comb honey, which should be shipped North before March. Extracted honey might become thin in the rainy season, but is generally sold in February or March. No poisonous reptiles except water-moccasins. Fleas to beat the world—can't get away from them—jiggers pretty bad, but no ticks nor bed-bugs. Grapes, figs, oranges, and vegetables grow splendidly, but he predicts that in the future the *comb* honey of Cuba will be the thing to astonish bee-keepers.

Large vs. Small Hives.—In a very interesting manner Adrian Getaz discourses in the Bee-Keepers' Review. Take two equal colonies, No. 1 being in a small brood-chamber, No. 2 in a large one. When the brood-chamber of No. 1 is full it commences storing surplus, while No. 2 continues filling its brood-chamber. If the flow is short, No. 1 gives a crop of surplus honey and No. 2 gives none. But Mr. Getaz, like Mr. Dadant, thinks the fair thing is to consider the second year. Instead of being equal in the spring, No. 2 is stronger, and builds up more rapidly in proportion to its numbers, has its brood-nest full as soon, and begins in super as soon or sooner than No. 1, and harvests as much or more in proportion to its size. There is a saving of time in manipulating; perhaps less feeding to do, and less swarming. If there is a light flow after the main flow, No. 2 may store surplus when No. 1 does nothing. In winter No. 2 consumes proportionally less stores and loses proportionally fewer bees.

Two-Story 8-Frame Langstroth vs. 10-Frame Quinby.—C. P. Dadant having said that it is better to have one story of Quinby frames than to use two stories of 8-frame Langstroth, Dr. Miller says in Gleanings he is afraid Mr. Dadant is right, but is anxious to believe him wrong because it is much more convenient to have the lighter hives. So, "by way of whistling to keep his courage up," he argues in favor of the smaller hives with smaller frames in two stories. The room can be limited in two as well as in one story, by using dummies. When a second story is given, the bees increase the brood-nest just as gradually as when frames are added one by one in the large hive, except that they hesitate to cross the space from the upper to the lower story. There is economy of heat in adding the second story, for the heat descends in the lower story only as the bees descend. While the large hives and frames may be better, they are not enough better to overbalance the disadvantage of their cumbrousness.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last. Better order at once, if you want a copy of this song.

Root's Column

No-Gob Foundation.

We Have it at Last.

It has been proven that wax in the base of ordinary foundation is not utilized by the bees, but is left there practically as it leaves the mill; and the result is, when drawn out into comb, the so-called gob, or fishbone, in comb honey.

Our New Thin-Base FOUNDATION

is exactly what its name indicates—foundation with a base as thin as natural comb, with heavy deep walls.

Fig. 7, herewith shown in cross-section from an actual photo, represents the new thin-base heavy-walled foundation running about 10 feet to the pound.

Fig. 13 represents the ordinary thin foundation with heavy base and scarcely any wall, about 10 feet: the heavy base, without modification, going right into the comb honey with very little change, and forming fishbone.

We have so far only small dies, and cannot afford to sell this product for less than \$1.00 a pound. Next year, perhaps, we shall have larger dies, and will make a corresponding reduction in price.

Seven or eight pieces, large enough to fill 44 sections, 15 cents, postpaid; 24 pieces, prepaid, 40 cents.

The A. I. Root Company
MEDINA, OHIO.

GENERAL ITEMS

A Little Experience With Bees.

I have kept bees for a long time in a small way with varying success, and without any particular system. For the last three years I have given them more attention, and have consequently been anxious to inform myself in the science of bee-culture. Realizing that a good paper devoted to the subject would be indispensable, I have selected the American Bee Journal as the most desirable.

I now have about 50 colonies, which I am wintering in a cellar. My hives are of my own plan and make, as are my surplus cases. I have seen none I like better, and none quite so handy and convenient. My hives are 14 inches wide, 17 long, and 11 deep in the clear, with 9 frames; loose bottom attached with hooks, $\frac{3}{4}$ opening with one-inch hole in the center of the front (for ventilation in winter). I use half board and half screen tacked over the front, raise the cover slightly, after removing the honey-board, and they are ready for winter quarters. The object of the inch hole is to provide ventilation in case the bees should become uneasy and fill the entrance with dead bees, as sometimes occurs. I have lost but one colony in three winters, so I am satisfied with my method of wintering.

As to foul brood, I am not informed, as I have never seen any, to my knowledge. I would like to know how to determine from external evidence the presence of foul brood.

The last season was a poor one for bees in this locality; mine averaged only about 30 pounds of comb honey, spring count. Very few of the old colonies produced any surplus. My bees weighed from 50 to 80 pounds, gross, when I put them into the cellar.

I am very fond of hunting wild bees, and have quite a reputation as an expert. I have found a large number of wild swarms (several hundred). H. B. KNOWLES.

Wiuona Co., Minn., Feb. 24.

Heavy Rains Near San Francisco.

We have now had four days steady and continuous rain. The earth is now so full of water that it cannot take up any more and it is running off where it can; in other places it lies in pools on the surface. We have not had so much rain at one time for years. Grass is growing wonderfully fast. It does not look as if less than a fortnight ago we were despairing of rain and crying "dry season." Prayers for seasonable rain were commenced in the Catholic churches when the season began to give indications of a dry season, and soon all the other churches joined in the prayer. It has evidently been answered. Four days without sun is something unusual here. This evening the rain is slackening off and giving place to a high fog. It may be that it is going to clear up. Well, it can do so now, as we have had all the rain we need. I should judge that we must have close to 20 inches. We had only 11 last year. W. A. PRYAL.

Alameda Co., Calif., March 24.

Makes His Own Hives.

This is the third year I have had bees, and I think I can say that so far it has been the hardest of the three. My bees had a flight yesterday (Feb. 18) for the first time since Dec. 1st. It was a very necessary thing for them to get out, as their stores were mostly buckwheat honey, and I saw that the hives were damp and the combs moldy. I think my hives are too tight. I have decided that bees don't want to be closed up too tight. My hives are double-walled chaff, the outside wall continuing single above the top of the brood-frames high enough to take in two supers,

SWEET CLOVER

And Several Other Clover Seeds.

We have made arrangements so that we can furnish seed of several of the Clovers by freight or express, at the following prices, cash with the order:

| | 5lb | 10lb | 25lb | 50lb |
|-----------------------------|-----|--------|--------|--------|
| Sweet Clover (melilot)..... | 60c | \$1.00 | \$2.25 | \$4.00 |

one being on and filled with chaff, and a cover over all. I think from appearance it is too close.

I want to say to the readers, and to those that should be readers of the American Bee Journal, that this is the third year I have taken this journal, and it bids fair to be the best of the three. I have been very much interested in Mr. Golden's method of producing comb honey, and his very unselfish way in giving it free and unrestrained to all alike, and I for one would thank him. My interest was first awakened by the article appearing in the first number of the year, then I took the previous volumes, as I have them bound and index, and read everything pertaining to the Golden method, and I have decided there is something in it.

I am young in the business, but I am in it because I love it, and am very fond of honey. I can't give it my undivided attention, but sometime I hope I may make it more of a business.

I have noticed some discussions as to the advisability of bee-keepers making their own hives. I want to say I for one believe in it, but not for all. I confess I am very particular to have a good job when it is done, and some of the bee-supply firms can do the best kind of work, and cheaper than most of us can possibly do it. But with others like myself, it is different. I have a nice little barn on my place which I use for a shop. I have a two-horse power engine and a combination circular saw, all of which I made, and by taking pains I can do pretty good work. So I say, if one is so fixt he has the advantage over others in the business. **NORMAN O. JARVIS.**

Madison Co., N. Y.

Hard Weather on the Bees.

We are having dark, damp weather at present. I am afraid for the bees. I have lost one of my colonies with the diarrhea already—a good one. 2 1/2 gallons of bees in it, and about 30 pounds of honey, nice and sealed white clover mostly. Our damp weather has continued since the middle of February, and I begin to feel shaky about the bees. **WILLIAM LYONS.**

Sioux Co., Iowa, March 14.

An Old Bee-keeper.

I am an old bee-keeper, and have reared a good many queens and sold them for \$5.00, and bought one queen for \$15.00. I bought my first colony of Italian bees for \$20.00 when they first came, but now they are low. I have transferred bees for many years. I went 40 miles to transfer, but now the seasons are poor and winters hard. I once had 50 colonies, and have now 10. Last year was very poor. Two years ago I got 55 gallons of honey from five colonies. **C. J. YOMER.**

Wayne Co., Ohio, March 23.

Heavy Loss Good Crop Prospect.

The winter loss in this part of the country is greater than ever known before. Some bee-keepers' loss is 25 percent, and some 50. I was very successful, for I wintered my whole apiary without the loss of a single colony. I never before had bees in as fine shape as this spring—plenty of bees and brood.

The prospect for a large honey crop was never better than it is this spring. Maple and elm are in bloom, and the weather is clear and warm. The bees are tumbling over each other bringing in pollen. Hurrah for the American Bee Journal!

Page Co., Va., March 24. **C. H. MAY.**

Worst Winter—Bitter Honey.

I appreciate the American Bee Journal very much, and have tried to get my friends to take it. This has been the worst winter I have seen here, the temperature went to 18 degrees below zero. I have at present 14 colonies, which have all come thru safely so far, tho I expect to have to

We mail it for 25 cents; or will send it FREE as a premium for sending us ONE NEW subscriber to the Bee Journal for a year at \$1.00; or for \$1.10 we will mail the Bee Journal one year and the Clipping Device. Address,

GEORGE W. YORK & COMPANY, 118 Michigan St., Chicago, Ill.

feed, as fruit-bloom is all killed, and the spring is so backward. This is not much of a honey locality, as for the last few years the greater part of the honey has been so extremely bitter, especially late honey. There is a weed known locally as "yellow-weed," which yields plentifully, a beautiful, light honey, but as bitter as quinine. The same weed also ruins milk. I will send a sample this year. ALBERT E. ISAAC.
Morgan Co., Ala., March 23.

A Correction--Lots of Rain.

On page 94 I am made to say: "The coldest it has been in the last six years here was 16 degrees below zero." I wish you would please change it to 10 degrees above zero.
I like the Bee Journal. We are having lots of rain. HERBERT PRUNER.
Douglas Co., Ore., March 23.

Good Weather for Polar Bears.

There seems but little prospect of getting bees out of winter quarters for some time yet. To-day the snow is two feet deep all over the bee-yard, and it is still snowing, accompanied by a strong gale from the north. If such arctic conditions continue much longer, the production of polar bears will be a more profitable industry in Minnesota than the production of honey.
WM RUSSELL.
Hennepin Co., Minn., March 25.

Endured a Hard Winter.

I have one colony of bees which I purchased last fall and packed with chaff on the summer stand, as nearly as the American Bee Journal instructed me as I knew how. They have endured a long, hard winter, but have taken occasional flights whenever the climatic conditions would permit, and I believe they are in good condition.
CHAS E HOOVER.
Whitman Co., Wash., March 13.

1898 Not a Total Failure.

The year 1898 was not quite a total failure. I began the spring with only 12 colonies, increase none, and I took off about 1,500 pounds of honey in the comb, while my neighbors, who cannot afford to take the Bee Journal, received little or no honey from their bees.
GEORGE A. KERR.
Kent Co., Mich., March 25.

Bees in First-Class Condition.

My bees are in first class condition, and had a good flight March 21, so they can stand being coopt up for a while yet. Some have lost some bees around here.
W. H. POTTORF.
Mason Co., Ill., March 23.

Bees in the Cellar, All Right.

The thermometer has ranged here from 12 to 24 degrees below zero, without any snow on the ground. The bees have come out pretty slim, where they were outside, some losing their last colony. I have lost 3 out of 6 that were in a small bee-house outside. Those I put into the cellar are all right. The cellar is the place for me to winter bees.
M. V. JEWELL.
Genesee Co., Mich., March 17.

Preserving Fruits with Honey.

In looking over the pages of the American Bee Journal, I came across a request for those who have tried preserving fruits in honey to give their experience. My experience is limited, and is confined to a few trials with grapes.
Trial No. 1.—Seven pounds of sound grapes on the stem packed in a stone jar. Make a syrup of 4 pounds of honey, 1 pint of good vinegar, with cloves and cinnamon to suit—say 3 ounces each: boil together

BIGGLE BOOKS

A Farm Library of unequalled value—Practical, Up-to-date, Concise and Comprehensive—Hand-somely Printed and Beautifully Illustrated.

By JACOB BIGGLE

No. 1—BIGGLE HORSE BOOK

All about Horses—a Common-Sense Treatise, with over 74 illustrations; a standard work. Price, 50 Cents.

No. 2—BIGGLE BERRY BOOK

All about growing Small Fruits—read and learn now; contains 43 colored life-like reproductions of all leading varieties and 100 other illustrations. Price, 50 Cents.

No. 3—BIGGLE POULTRY BOOK

All about Poultry; the best Poultry Book in existence; tells everything; with 23 colored life-like reproductions of all the principal breeds; with 103 other illustrations. Price, 50 Cents.

No. 4—BIGGLE COW BOOK

All about Cows and the Dairy Business; having a great sale, contains 8 colored life-like reproductions of each breed, with 132 other illustrations. Price, 50 Cents.

No. 5—BIGGLE SWINE BOOK

Just out. All about Hogs—Breeding, Feeding, Butchery, Diseases, etc. Contains over 80 beautiful half-tones and other engravings. Price, 50 Cents.

The **BIGGLE BOOKS** are unique, original, useful—you never saw anything like them—so practical, so sensible. They are having an enormous sale—East West, North and South. Every one who keeps a Horse, Cow, Hog or Chicken, or grows Small Fruits, ought to send right away for the **BIGGLE BOOKS**. The

FARM JOURNAL

Is your paper, made for you and not a misfit. It is 22 years old, it is the great boiled-down hit-the-nail-on-the-head,—quit-after-you-have-said-it, Farm and Household paper in the world—the biggest paper of its size in the United States of America—having over a million and a-half regular readers.

Any ONE of the **BIGGLE BOOKS**, and the **FARM JOURNAL** 5 YEARS (remainder of 1899, 1900, 1901, 1902 and 1903) will be sent by mail to any address for **A DOLLAR BILL**. Sample of **FARM JOURNAL** and circular describing **BIGGLE BOOKS** free.

WILMER ATKINSON. Address, **FARM JOURNAL**, PHILADELPHIA.
CHAS. F. JENKINS.

A MOST WONDERFUL OPPORTUNITY.

for 20 minutes, skim well, then turn hot over the grapes and seal.

This recipe I found in "Honey as Food and Medicine" [A pamphlet now out of print.—Ed.], and it was added that apples, peaches and plums may be preserved in the same way. The grapes thus treated were good enough for anybody, and kept for a long time.

Trial No. 2.—I put a lot of real nice bunches of sound grapes into a lot of real nice honey, and the result was that I spoiled both. My recollection is that I had something that resembled vinegar more than anything else. EDWIN BEVINS.
Decatur Co., Iowa.

Bees Wintered in Good Shape.

My bees have come thru the winter in fine shape. I am feeding bran now, and you ought to see them carry in the bread. The weather is lovely, and we look for an early spring.

F. D. HAINENKRATT.
Otero Co., Colo., March 19.

Having a Good Rain.

We are just now having a good rain—the first since Jan. 12. It will have to rain a great deal more than it usually does to make honey in the late buckwheat localities.

F. J. FARR.
Los Angeles Co., Calif., March 17.

A Big Little Honey-Eater.

Seeing the question in the American Bee Journal, as to how much honey one can eat at one meal, I thought I would tell how much I could eat. I have often eaten one pound of honey at a meal, and I am only 13 years old. I wasn't trying to see how much I could eat, but I ate it because I wanted it. JOSIE M. TICHENOR.
Crawford Co., Wis.

Good Prospects for Honey.

We have had a very cold winter here. Bees have come thru in poor condition. There is no brood in the hives to amount to anything now. Very late spring, and no flowers yet. Bees will be late in brood-rearing, the latest I ever saw. Prospects are good for a honey crop thus far.

G. D. HAWK.
Sullivan Co., Tenn., March 21.

Fruit-Trees in Bloom.

Fruit-trees are now in full bloom. The bees are busy, and I think that prospects are favorable for a good season.

J. G. STEWART.
Donna Ana Co., N. Mex., March 20.

Wintering in Good Condition.

My bees, and those of Mr. L. C. Watts, seem to be wintering in good condition thus far, in cave and cellar. G. H. SCHRAM.
Jasper Co., Iowa, March 25.

Not An Encouraging Report.

My bees are in fair condition now. They have been carrying some pollen from the elms when the weather is suitable. I have lost one colony so far this winter. My honey crops in the last three years have been just medium. In 1896 I secured 214 pounds of comb honey and 240 pounds of extracted honey; in 1897, 126 pounds of comb honey and 51½ pounds of extracted, from 50 colonies; in 1898 I secured 315 pounds of comb honey and 273 of extracted, from 53 colonies. This isn't much of a country for honey, that is, for quantity, but the quality is all right. Our honey is generally fair, and fine-flavored, but not enough of it to pay for the trouble of taking care of the bees, which in this part of the country, except in the mountainous parts, don't get very much surplus honey.

The Farm Journal and the Bee Journal.

Offer No. 1. We will club the Bee Journal for one year and the Monthly Farm Journal for five years as above all for \$1.40; the Farm Journal alone is 50 cents a year.

Offer No. 2. Send us ONE new subscriber for the Bee Journal for a year (at \$1.00, and we will order the Farm Journal for you for 5 years as a premium).

Offer No. 3. Or, send TWO new subscribers for the Bee Journal for the balance of this year at 60 cents each, and we will order the Farm Journal for you for 5 years as a premium.

Better apply soon, as we have only a limited number of 5-year FARM JOURNAL subscriptions to offer. Address,

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.

AMERICAN BEE JOURNAL.

ESTABLISHED IN 1861 OLDEST BEE-PAPER IN AMERICA

DEVOTED EXCLUSIVELY TO THE INTERESTS OF HONEY-PRODUCERS.

39th YEAR.

CHICAGO, ILL., APRIL 13, 1899.

No. 15.

The Afterthought.

The "Old Reliable" seen through New and Unreliable Glasses.
By "COGITATOR."

NOT ENTHUSED OVER EUCALYPTUS.

Mr. Pryal's talk and pictures about the eucalyptus trees (page 129) are very interesting indeed; and yet I do not find myself getting *enthused* about them much. If a tree looks like a beanpole, and if we have to say to a fellow, "This is an excellent medicine," in order to make him eat the honey, 'pears like that bee-folks might go further and do better in the matter of tree-planting.

FEEDING EVERY TENTH HIVE.

Page 132. What shall we say about Mr. Aldrich's plan of feeding every tenth hive, and making the bees store honey for the other nine? I should have doubts about their doing so much storing readily, and fears that bees so overworked in the fall might "peter out" before spring. Still, I am conscious that these may be empty and needless apprehensions. I don't *know* much about it.

A TRICK OF THE HONEY-COMMISSION MEN.

There is an idea dropt by Mr. McNay, on page 132, that we can hardly afford to let slip. Send a commission man honey outright and he puts it in the back part of the store, to sell when he gets other things cleared up. Make him pay you a good advance on it, and (just as naturally) he sets about selling it at once, because he wants to get his money in hand again. See? Quite honest men have been known to look out for their own interests, don't you mind?

FREQUENT FLIGHT-DAYS AND GOOD STORES.

You're just like all the rest of us, Comrade Dasant; crowing loudly before we're out of the wintering woods. Frequent flight-days are indeed the best thing we can possibly have to get thru the winter on, *except one*. And that one thing is "pizen on us" this winter. Not for many years has the quality of the winter stores been so poor as this time. If spring should prove late and trying many of us will suffer, I fear. Good plan to count our mercies, however. Had this winter been as destitute of flight-days as some winters are, many localities would scarcely have had a bee left by this time.

A QUEEN'S SPRING EGG-LAYING.

Whoever has stood before a tired audience, burdened with the duty of interesting them notwithstanding their weariness, can sympathize with Mr. Doolittle as he began the brilliant address reported on pages 133, 146 and 165. We're all glad that the "scare streaks" up his legs didn't make him sit down. When a really competent lecturer talks

on the rudiments of a thing he is pretty sure to let out some facts which those advanced in the art can feed on with interest. Probably not one in a hundred of us knew that the queen begins in the spring by laying about ten eggs a day for awhile. If Cogitator had been driven to a Yankee guess he would have guessed about half-a-dozen eggs the first day, and a couple of hundred the second. But of course Doolittle is right. In the observation of little things he is one of the most accurate observers.

DIFFERENCE IN TASTE OF HONEY.

As to the question of the taste of Italian honey vs. the taste of the other kind, which Mr. Bevins sails into so valiantly (page 134), Tater would incline to go further, and deny the alleged facts *in toto*. Different races, strains and colonies differing in pretty much every imaginable way, now for the better, and now for the worse, the bees a fellow is enthusiastically in favor of store (of course) the best-tasting honey for him. That was a sharp shot of B.'s where he reminds his antagonist that very many flowers hang bottom side up, so the heaviest nectar would settle into reach, instead of out of it, if any such separation went on.

PROOF OF GENUINENESS (!).

In the ninth boil-batch page 138, Holtermann hits the bull's-eye (or say the cow's) with that milk story. Leaving propolis on the sections to prove genuineness next door to proving butter by the hair in it and milk by that cow-dung flavor often gently alluded to as the "taste of the barn."

ODOR OF TAR FOR FOUL BROOD.

Won't do to trust one swallow for a summer, but if many swallows get the same results as Loyalstone, on page 138, we shall have something new of distinct value in fighting foul brood. Just powerfully impregnate wax designed for foundation with the odor of tar.

THAT "EAR-WAX FOR STINGS" STORY.

Ear-wax the best remedy for stings, eh, only so apt to be unattainable. Page 140. Let me suggest, Mr. Hermaunce: If all the bee-folks should warm your ear, by telling you what they think of your whisky remedy, it would melt out wax enough to give you a start in the ear-wax supply trade.

THE QUESTION OF FACING HIVES.

That boy Miller, on page 160, was being switcht not for facing hives the wrong way, but for teaching that the direction made no difference. And, lo, he thinks to get off by showing that a big bee-man (the biggest one of all, in fact) considers facing quite important. No, my boy, if you could get Doolittle and Cogitator to play the two-ram act, that wouldn't help you any. Furthermore the chances are that they won't butt. Doolittle lives in a very cool climate, high altitude, and pretty well north; and if he decides that the days when sunshine right square in front does harm are so very few that the days when direct sunshine does good greatly overbalance them, Tater won't deny it. And if Tater finds very few summer days when the sun after 11 is any good, and many days when it is a sweltering nuisance, I don't believe Doolittle will put down his wooly paw and

charge. Whole thing a matter of climate. Nobody in the North has any good word for a north facing; but presumably in Cuba (if hives had to be left awhile without shade) north facing would be the only proper way. The matter is very simple indeed. To get the morning sun and not much else, face east. To get the most sun possible, face south. To get the least possible, face north. If your honey mostly comes in afternoons, and afternoons are apt to be too cool, face west.

MR. GETAZ PROBABLY TWICE CORRECT.

Cogitator agrees with Adrian Getaz, page 145, that dead bees in the outer spaces, in out-door wintering, are dead of cold—rest of the world to the contrary notwithstanding. And quite possibly Mr. Getaz is correct in calling stimulative feeding and brood-spreading two equivalents, either one of which may be used, but not necessarily both at once. "Tater's a little shy of both.

BRUSHING HONEY INTO COMBS.

Another way to get honey into empty combs for feeding purposes—brush it in with a paint-brush. Maybe now that's a good idea. Thanks to Mr. Bair, page 148.

MARKETING HONEY—PECK'S PECK OF TROUBLE.

Mr. Peck's peck of trouble, on page 149, is one where with many of us have been pecked—good local sale-route patiently worked up (8 cents a pound), and, presto, a youngster strikes in at 7 cents. The satisfactory remedy is rather hard to find. Mr. Peck thinks "educating him" with bee-journals, etc., only makes him worse—surer than ever that *he* can get rich on 7-cent honey. Whatever we do, let's not get mad and hate the boy in our hearts; he's only at what the world calls "business." I put my retail figure at 7 cents years ago, and the 6-cent boy has not yet turned up. If he should, my honey would be 6 cents directly. I admire, rather than hope to imitate, the once-a-year visited route, and the uniform 25-pound package. Too late to make my route stand that now, sure. Smaller packages and more frequent visits are more to the mind of the average customer; and once-formed habits do not change easily to habits a little less agreeable.

30,000 TONS OF COMB HONEY.

Honey statistics (in this country at least) are apt to be disgustingly unreliable, and far off from the truth; but when the big makers can be got to report how many sections they made we have *something* to tie to. The 30,000,000 that Wisconsin made is a big lot. If we may credit all the rest of the Union with as much more, we have an indirect hint of 60,000,000 pounds of section honey. Page 152.

DEFECT IN MICHIGAN'S FOUL BROOD BILL.

That Michigan Foul Brood Bill looks excellent in the main, but seems to have one gross fault. The minimum of punishment under it is a 50-dollar fine; and this can be inflicted on a person not to blame at all, only densely ignorant. Better split things. The 50-dollar minimum just so as it ought to be for the man who resists the inspector; but for selling foul-broody bees or honey better let the court decide just what the measure of guilt is, and not compel injustice by a minimum. COGITATOR.

The Omaha Convention Report ran through 14 numbers of the Bee Journal, beginning with the first number in October, 1898. Now we have on hand quite a number of complete sets of that report, which we will mail for just 10 cents each. That is, 14 copies of the American Bee Journal for only a dime. There are doubtless a good many of our new readers who will be glad to get that fine report.

Langstroth on the Honey-Bee, revised by the Dadants, is a standard, reliable and thoroughly complete work on bee-culture. It contains 520 pages, and is bound elegantly. Every reader of the American Bee Journal should have a copy of this book, as it answers hundreds of questions that arise about bees. We mail it for \$1.25, or club it with the Bee Journal for a year—both for only \$2.00.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last. Better order at once, if you want a copy of this song.

CONTRIBUTED ARTICLES

Poor Stores and Want of Air Cause Loss.

BY WM. M'EVROY.

MISS FANNIE C. DAMON, Middlesex Co., Mass. Your letter of answers to my questions was received some time ago, and I will now give you my opinion of the cause of the sudden death-rate of your old bees in the winter, and the unhealthy condition of your colonies in the fall. Want of air in winter and poor stores in the fall were the causes of all your loss of bees.

The closing of the entrances of your colonies with ice and snow in February, 1898, was a very serious matter, because it left the bees to depend entirely on what air they could get thru the packing on the tops of the brood-chambers. When I read of the large death-rate of bees among your colonies—all dead in six, and only a small quantity alive in the other 11 hives—I felt certain that you had too much weight on the "safety valve"—too much close packing on the brood-chambers, when the entrances of your hives became closed air-tight with ice.

To make sure that I was not mistaken, I wrote to you asking how many inches of packing you had on each brood-chamber, and what it was composed of. When you answered saying that you first put on a covering of burlap, and on this a woollen mat, then an oats chaff cushion five inches thick, and above this from two to five inches of leaves, which made the tops of the brood-chambers almost air-tight, I knew well that it would not do to let the entrances become closed solid with ice and frozen snow, and remain in that condition for several days with so much packing on top of the hives, because the steam that would arise from the breath of the bees in that fix would dampen the packing above, soften the capping on the sealed stores, thin the honey in the unsealed cells, and injure the keeping qualities of a part of the honey, and particularly so with honey gathered from fall flowers.

Miss Damon, I see by your letter before me, that while your hives were bankt up with snow in February, 1898, it rained until it filled the snow with water, and then froze the snow solid with a crust of ice on it strong enough to bear up a horse, and after that everything seemed to be as hard as adamant. Very true, and that same very extremely cold dip froze the damp packing above the bees, and closed the entrances with ice and snow, and then the bees began dying by thousands for the want of air.

As you say, you had been for years very successful at wintering bees, and I don't wonder at it because you not only gave your bees plenty of stores to winter on, but had taken the greatest of pains to pack your colonies in first-class order. If you had only thought of it and kept the entrances to all of your hives clear, so that the bees could have had plenty of air, your colonies would have wintered just as well as the others had done in the past.

In reading over your letter of answers to my questions, I find that you prove my opinion to be correct as to the cause of your loss of bees in winter, and the dwindling in spring, when you say, "But the only colony of mine that came thru safely was in a cooler place, and not so bankt with snow, and had more ventilation at the back of the hive, as the loose bottom-board had become warped." Ventilation was the very thing that saved that colony, and it was a pity that your other colonies did not have as much ventilation as that one.

Now about the combs with honey, which you took such pains to save so nicely and so well. Very few of our best bee-keepers would have thought of that. I was anxious to know if your bees had not gathered considerable honey from fall flowers in 1897, which I believed they did. You replied, saying, "The bees did gather a great deal of fine thick golden-rod honey in the fall of 1897." The keeping qualities of the different kinds of honey in the comb varies a great deal when exposed to dampness. Some will keep in fair condition under trying circumstances for six months, while some other kinds of honey won't keep as good for three months if exposed to the same amount of dampness. Some of the combs which you took out of the dead colonies had more or less of the honey in them, which your bees gath-

ered from fall flowers—a class of honey that doesn't keep as well as clover after the bees almost wintered on the combs that it was in.

If these combs had been mine, *I would have extracted the honey out of every one of them*, right after I took them out of the hive, and then heated the honey until a good waxy foam raised on top of it; after skimming it I would have fed the honey to the bees *in the evenings* when the bees were gathering little or no honey during the day. The bees would have fed the most of the honey direct to the larvae just then, and by steady and regular feeding at such times the most of the old honey would have been profitably used up, a very much larger quantity of bees reared, and not one cell of dead brood would be found in any colony during the time the feeding was going on.

Miss Damon, it is my opinion if you had extracted every particle of honey out of every comb last spring, before you used any of the combs, your colonies would have been all right last fall. When your bees began dying at a rapid rate last fall, a prompt removal of every comb for combs with better stores is what should have been done, and if these could not have been had, I would have crowded the bees on a limited number of nice empty combs and then fed them plenty of granulated sugar syrup until they filled them and sealed them over nicely, and then all would have been right.

Woodburn, Ont., Feb. 27, 1899.

Wax-Secretion, Etc.—A Reply to Cogitator.

BY R. C. AIKIN.

ON pages 2 and 3 appears an article from myself in which I referred to comb-building and wax-secretion and their effect on the yield of surplus. I referred to certain doctrines that have been commonly accepted in the past as correct, tho now largely disbelieved, viz.: That 15 to 25 pounds of honey are consumed, over and above that which would otherwise be, for each pound of wax made into comb.

I also said that I did not believe that so much was lost to the bee-keeper, but "that all normal colonies, when gathering nectar and ripening and storing the same, secreted more or less wax regardless of the need of it," inferring that it might be as well to let the colony build some comb. I further said that "a 10-frame hive, Langstroth size, takes nearly two pounds of wax to construct its combs. Surplus honey from the same hive to the amount of 25 pounds means about three pounds of wax secreted, which, at the ratio of 15 of honey to one of wax, means 45 pounds of honey consumed in comb construction."

I also said, "the brood-combs should contain not less than 35 pounds" (which is surely very reasonable, for I have known 10-frame hives, when full, to contain over 50 pounds of honey), "which, added to the 25 pounds of surplus received, would make 60 pounds." Is there any over-drawing or rash statement in that? There is a plain statement that a colony has built all its comb and stored 60 pounds of honey.

Now, if it be true that the wax used in these combs would cause the consumption of 15 pounds of honey to one of wax produced, then surely the colony, if no wax was secreted or comb built, but instead had been given all combs needed to receive all they gathered, that stock of honey must at least equal the 60 pounds plus all consumed to make wax (comb).

I have a large solar extractor. I once cleaned this and loaded it with 100 Langstroth combs, putting in frame and all. After removing the wax and refuse, the solar was again loaded with 100 combs as before. These were nearly all natural combs, and yielded about 18 pounds of wax to the 100. I do not know how much wax was in the refuse, nor how much soaked into those 200 brood-frames, but surely some. This corroborated the statement of others, that about two pounds of wax would build comb in 10 Langstroth frames.

Since the publication of that article, on pages 2 and 3, I have made two more experiments. Honey from 25 sections 4 $\frac{1}{4}$ x4 $\frac{1}{4}$ x1 $\frac{1}{8}$, and full separator, was cut out and melted, and a second 25 treated likewise. I neglected to put down the figures, so I have them somewhat indefinitely in my mind, but I remember distinctly that one lot gave me 17 pounds of honey, and the other a little more—I think it was 18 or 19 pounds—and of wax one gave 14 ounces, and the other either a little more or a little less—I think a little more.

The section experiment shows clearly that very close to one pound of wax is used to hold 25 pounds of honey. This

is fully in line with the two pounds to 10 Langstroth-frame combs. Counting the necessary waste in the melting of the 100-comb lots, I should say that my estimate of three pounds of wax in the brood-chamber and a 25-pound surplus of section-honey stored as indicated in that former article, was not overdrawn one bit. And more, the addition to the 60 pounds of 45 more represented in the wax (105 in all) should represent the honey gathered by that colony if the 15-to-1 theory is correct.

I further stated that *if it was true that bees were kept from fielding to secrete and manipulate this wax*, that an additional amount must be lost in that way, and I guess that at $\frac{1}{3}$ the total honey gathered, putting it at $\frac{1}{3}$ of the 60 pounds, whereas it should have been $\frac{1}{3}$ of the 105 or more. According to the basis of figuring used, I said, "A swarm hived and building all its comb and yielding a 25-pound surplus, should, if given all the comb it could use, have yielded, in addition to the 25 pounds, 65 pounds more—a total of 90 pounds of surplus."

At the bottom of page 81, and top of page 82, Cogitator makes an unfair reference to me, and misrepresents what I said. I did not say "that 25 pounds of surplus comb honey means three pounds of wax secreted," and I hereby demand that Cogitator come down on his knees and receive his just reward, and that hereafter he will not set me up in such a light as he there does.

A certain preacher wisht to condemn a certain fashion in hair-dressing, and took for his text, "Top-knot come down!" whereas the whole text was, "Let him that is on the horse-top not come down," etc. To take detach sentences, and sometimes even paragraphs, would make any of us appear as fools.

No, sir, Mr. Cogitator, I stick to it that 10 Langstroth combs and 25 pounds of section honey represent just about three pounds of wax. You admit that "the current ratios should be hauled down a long way," so we will haul it down to 8 $\frac{1}{3}$ instead of 15, and still the case I supposed would give 50 pounds instead of 25, which ratio your humble servant would haul down at least by another 4 $\frac{1}{2}$.

Now suppose the colony to be an old establish one, having all its brood-chambers full of combs, only that in sections to build. Take your own figures of one pound of wax to 20 of honey, and let us figure some more. If a pound of wax costs five pounds of honey, then the ratio as between that stored when comb is built, and when no wax-secretion is necessary, is 20 to 25. At 10 it is 20 to 30; at 15, 20 to 35; at 20, 20 to 40. I will take the 5 to 1 as the nearer correct of any of them, and if you or any other cogitator can prove me wrong, just pitch in.

Beware that you do not fall into the error of accusing me of saying that there never are conditions under which the yield as between comb and extracted will not exceed the ratio of 4 to 5, but as far as wax-secretion alone concerns the question I challenge you to prove that I am not right. I have repeatedly made this challenge—or one very similar—and in something like two years it has not received an attempt at answer.

Come over some evening, Mr. Cogitator, and we will play checkers and talk bees, and have a good old bee-convention. Will you come? Larimer Co., Colo.

The "Long-Idea Hive" and Its History.

MR. YORK: I would like to ask in regard to the hive Mr. Poppleton uses. What is the size of the frame, and how many does he use for extracting? I have a few one-story hives with frames 11 $\frac{1}{2}$ inches deep and 12 $\frac{1}{2}$ long, with 16 in a hive. Would you consider it a good hive for extracted honey? There is no surplus arrangement on top of this hive, the honey to be extracted from the outside brood-frames.

F. EATINGER.

[We referred the foregoing questions to Mr. Poppleton, who kindly replied as follows: EDITOR.]

EDITOR YORK: At your request, I will try to answer Mr. Eatinger's questions.

The frames I use are what is commonly called the "American frame," said to be 12 inches square, but mine are actually 11 $\frac{1}{2}$ x11 $\frac{1}{2}$ inside measure, being practically the same as Mr. E. has. In my opinion a shallower frame than these should never be used in single-story work.

Sixteen frames are not enough. My hives will hold 24 frames each, with a thin division-board in each end. One of the advantages of this method of working bees is that

the number of combs in use can always be adapted to the size and needs of each colony. When working with my bees, I almost always have empty combs within reach, and to every colony I find with too few combs I add as many as are needed, be it one or more, and take away from any that have more than they need.

My colonies occupy all the way from 3 to 24 combs each, according to their strength, but I consider one that needs only 16 combs during the honey season as not being up to standard.

If I were again to keep bees in Iowa, and not practice migratory work, I should use hives that would hold three or four frames more than do the ones I am now using.

The Long-Idea hives were referred to in "Beedom Boiled Down," in your issue for Nov. 10, 1898, also a statement from Mr. Gallup that the two he tried were comparative failures. See article in Gleanings, page 13, of last year, for a history of these hives, origin of the name, and also reason why Mr. Gallup failed with them. The Gallup frame is not suitable for working in that manner, his own method of using that particular frame being the best.

Dade Co., Fla., March 28. O. O. POPPLETON.

[The article in Gleanings, to which Mr. Poppleton refers, reads as follows:—EDITOR.]

On page 634 of Gleanings for Sept. 1, Mr. Doolittle gives a version of the history of "Long-Idea" hives, and some remarks on their use. While the history of the origin of any of our implements or ideas may be interesting, they are, of course, not of practical value; but I feel very much like trying to correct the historical part of Mr. Doolittle's remarks.

About 1870, Gen. D. S. Adair, of Kentucky, devised and (I think) patented what he named the "New-Idea" hive. This hive was a long single-story one with the entrance in one end, at the side of the frames, instead of the ends, as commonly practiced. The "new idea" of the General was, as I understood it, having the combs containing brood all in the back end of the hive, with surplus honey arrangements all between entrance and brood, compelling the bees to pass thru the surplus honey part of the hive to reach the brood, instead of thru the brood-nest to the surplus honey, as in tiered-up hives.

I do not know who first changed from Gen. Adair's end entrance to having an entrance in the side of hives, and brood-nest in the center instead of in the back end; but I think the change was made and experimented with by a good many of us at the same time. It was not Gen. Adair, who gave the name "Long Idea" to the hive. I have always thought the name was first given to it in derision; but as no other yet used describes the hive so well, it has become the recognized name.

The discussion over these hives occurred when I was first starting my apiary in Iowa; and after trying both styles for a year or two, I adopted the long single-story hive, and still use it, not having a single double-deck hive in my apiaries. I used about 500 double-story hives for two years in Cuba, and was very glad to return to my own style. I would no more think of using a two-story hive for extracted honey than Mr. Doolittle would think of using the single story.

The truth is, Mr. D. probably has no knowledge of a properly made single-story hive. Neither the Langstroth nor Gallup frames can be successfully used in such manner. To use the right amount of combs in either of those frames will spread them out too much—doesn't leave them in as compact a form as they should be for successful use. I have told a great many bee-keepers who ask my advice, not to attempt to use shallow or small frames in such a way. Some of the foreign bee-journals, according to a review of them by Mr. Thompson, have lately been discussing this matter quite fully, and the conclusions they arrived at were similar to my own—that only deep frames were suitable for use in such hives.

Let me review Mr. Doolittle's objections very briefly. I can work a single-story hive much easier than a double story. The extra depth of my frame, and a little higher stand makes the top of the hive the same height from the ground as the top of a two-story Langstroth. I shake my bees inside, not on top of my hives, and avoid the trouble of crawling bees he speaks of. If I remember rightly, I used to be as successful as the average of bee-keepers in wintering my bees in Northern Iowa, and I used the long hive entirely. Mr. D.'s non-success with only two hives to the contrary notwithstanding.

Dade Co., Fla., Nov. 18, 1898.

O. O. POPPLETON.

CONVENTION PROCEEDINGS

Report of the Chicago Bee-Keepers' Convention.

BY A SHORTHAND REPORTER.

(Continued from page 214.)

GETTING THE PUBLIC TO EAT HONEY.

QUES.—What can be done to get the public to eat more honey?

A Member—Sell them better honey.

Dr. Miller—There is much in that. At one time I had some very poor honey-dew—miserable stuff. I put it on the market and insisted people ought to buy it because it was honest honey, gathered by the bees. I hurt myself greatly by that. If you want people to eat honey, you must give them good honey. There is a great deal of very poor extracted honey put on the market; I don't blame people for not liking it; if they get good, ripe honey they will use more of it. The quality of the honey has a great deal to do with the public consuming a large quantity. Give them a good article and they will like it and use it. There is some honey so poor that they ought not to like it; then there are other things, and we might take up the whole afternoon arguing on this, and I would advise you to suggest thru the American Bee Journal any time what you may have found to help increase the consumption of honey; but you will find that a great deal lies in giving the public a good quality of honey.

Dr. Peiro—There is another reason for it; the chief reason is, people don't know anything about honey. Where can you get it? What does it cost? Many such questions are asked about honey. People don't read the bee-papers, and they are the only journals that say anything about it. It needs some stirring up—some advertising. I don't see many advertisements; in fact, the honey is all right if the people only knew it was all right.

Dr. Miller—It is not all right. Some of it is unripe.

Dr. Peiro—I mean honey; I don't mean fraud honey. I don't care what you have to dispose of, if you don't advertise it in some way you are going to "get left." I think the problem to-day is, how to reach the public. You will not sell it unless you interest the public in it.

MAINTAINING A CERTAIN NUMBER OF COLONIES.

QUES.—If you have a field that will normally support 100 colonies, and we call this a working capital during a series of years how near can this working capital be maintained?

A Member—If I understand the question, I should say it can be entirely maintained.

Dr. Miller—The question is, how nearly can it be maintained?

Pres. Beers—A hundred colonies ought to keep 100 colonies going.

Dr. Miller—If it will normally support 100 colonies, how nearly can those 100 colonies be maintained? As I understand it, how long will it take to run out this 100 colonies? With proper management I should say those 100 colonies ought to be kept up year after year. You hear it spoken of sometimes as bees running out. Here is a man that had so many colonies, and got along so and so for a number of years, and then run out; but I think with proper management in breeding, 100 colonies, without any fresh blood being thrown in, might be kept up.

Mr. Moore—Dr. Miller, take the 100 colonies you had in 1888, how near has that 100 colonies maintained itself without outside money of yours put in for any purpose up to now, good and bad years?

Dr. Miller—I think I partly understand you, it has partly supported myself and family.

Mr. Moore—That 100 has given a net income of so much a year?

Dr. Miller—They have given something, certainly. I don't mean that the 100 colonies supported myself and family—they couldn't do it; but that 100 colonies as a working capital will give an income.

A Member—It will average for 10 years an income?

Dr. Miller—Certainly; it has for 35 years.

WHAT ABOUT APIS DORSATA ?

QUES.—Do we want the importation of the *Apis dorsata* from the new American territory—the Philippines?

Mr. Hammersmark—I think if we were familiar with it we would want it. I think we would all vote for it if it had a longer tongue and could be domesticated.

QUES.—If they build only a single comb would it be worth while? Would they build a number in a hive?

Dr. Miller—I don't know, unless you get them under stress in the hive to do differently; that is what they do left to themselves.

Dr. Peiro—I would like to ask if the long tongue is all they have in their favor?

Dr. Miller—There might be a decided advantage in this because of the red clover; it certainly would be a desirable thing where the red clover is plenty, to have a bee that could get the honey from it. If *Apis dorsata* can be domesticated, there would be a gain; but if it cannot be domesticated, or cannot live even tho it should be brought into this country, it would be no gain; because even tho it could be domesticated it might not be able to stand the climate here.

A Member—If it is a fact that they are very heavy wax-gatherers, would they not be absolutely useless to us? They would be all right for the extractors, for those that extract honey, but not for the comb-honey producers.

Dr. Miller—You think the comb would be too heavy?

A Member—I don't believe you could get enough honey from them, and you would have to sell it at a lower price. It would not be as good for eating purposes. You would have to gather the wax up and put it at the side of your plate. They might be all right in this country for those that run for extracted honey alone, but for comb honey, what I understand of them, they would be perfectly useless.

BOARD OR CUSHION OVER FRAMES IN WINTER.

QUES.—What is best, a board or cushion over frames in winter?

Dr. Miller—That depends a little upon what there is above the board or the cushion. Perhaps taking it in general, the cushion may be better. There may be at the present day a tendency to have a single board cover over the bees; the objection to that is, that it is cold; that the heat is conducted away from the bees thru that single thickness of board, and really we need a different hive-cover from what we have—one that has a thin board, and something like an air space. There are some advantages in having a single board cover, and perhaps there are so many that it is better not to use the cushion at all; a great many don't use it, because you can have it summer and winter the same; but as far as bees are concerned I suppose there is an advantage in the cushion, as it is a better non-conductor, and if you have it so the air can get thru, the moisture will escape and not be condensed in the hives. So in answering that, which is the best, I should say the cushion is the best thing if only the comfort of the bees is to be considered, but there are so many other things in the case that I prefer to have a board cover, and my bees are all covered with board covers now.

COLOR OF HIVES IN SUMMER AND WINTER.

QUES.—Would it be advisable to have your hives black in spring and fall, and white in hot weather?

Dr. Miller—Possibly. In the spring and fall you want to get the heat from the sun, and the black will absorb the heat better than the white; and in the hot days in summer you will have the white to keep the hives cool. If you have the hives in a dense shade, it does not matter much what the color is. If you have them out in the sun, there would be a decided difference, but if well shaded there won't be that difference. Many think that if you have your bees in dense shade then you will have them cool, and there will be no danger of combs melting down. The most combs I ever had melt down was in a place where the sun didn't shine all day long.

Mr. Moore—Mr. G. M. Doolittle has a building arranged for ripening his comb honey; he has it painted black, with a southern exposure, and he is able to keep it an even temperature for weeks. Black is the highest absorber of the sun's rays, white the least. Black takes it all in; white glances it off.

Mr. Clark—What is the thickness of his walls? If the walls were double thickness, take a one-inch board painted black, then fill in with sawdust or packing, then a board inside of that. I could imagine the black retaining the heat and causing an even temperature; it must be specially built, painted black, to keep that even temperature.

Dr. Peiro—Practically, does it pay to paint the hives, say twice a year? Is the amount of paint required more than offset by the good it may do?

A Member—Doesn't that fool the bees when they get into a white hive and then a black one?

Dr. Miller—So far as fooling the bees is concerned, you need not count on that, because you paint them at the same time. The other is practically a question we have to meet. Is it a desirable thing to paint the hives? If I lived in Cook County, the probability is that I would have all my hives painted; but I live far out in the country, and don't have my hives painted.

Mr. Moore—How are they shaded?

Dr. Miller—Some of them are shaded, some of them are out in the sun; if trees would never die they would all be shaded. Mr. Doolittle thinks he is very sure about it, that he would not have his hives painted if you would pay him, because he thinks the bees are better off in unpainted hives. I think he is right, but I don't feel as sure as he does.

A Member—Don't you think the construction of the hive has much to do with whether they are painted or not painted? Some hives are only single wall; some double; the double are better painted than not painted.

Dr. Miller—Perhaps there may be something in that; I can't say. I don't know that it would make any difference to the bees whether double-walled hives were painted or not. So long as you are talking about single-walled hives I would not have them painted.

Mr. Moore—I have experimented a little this summer, and I am dead sure what I want, but I don't know how to accomplish it. I want my hives unpainted in the spring and fall, and I want them white in the hottest weather, because the white paint will protect the hives from the excessive heat. How can I have black when I want it?

Pres. Beers—Paint them twice a year.

Dr. Miller—Of course it would be too much expense and trouble painting twice a year; you can accomplish that by shade boards to a large extent. I very much doubt if you would care for them in the fall, or in the spring; in the spring you want the benefit of the heat, and to let the sun shine directly upon the hives. Suppose you have a single-hive, you get the heat and are all right in the spring; that part is easily managed, but now comes the summer, and you want to have them protected from the sun. If you live out in the country where you can get long slough-grass, put a good armful on the hive, and put a stick of fire wood on that. I don't know of a better covering, and it is a good non-absorbent; it gives shade and protects from the heat of the sun. You can put some kind of a board covering on, a temporary rough one, but I believe I would a little rather have long-grass covering.

The convention then adjourned to meet the first Thursday in March, 1899.

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Increasing and Italianizing Colonies.

1. My bees are hybrids and I want to Italianize them this year; this is my plan of doing it—will it work all right?

I want to send for a tested Italian queen early in the spring and introduce her to one of my hybrid colonies, and as I am going to increase by dividing this year, I thought, by swarming-time, I would close all the hive-entrances of the hybrid colonies with drone-excluders, so that the young queens from the nuclei would be mated with one of the drones from the hive having the tested Italian queen. Then to Italianize those colonies from which I built up the nuclei (for the queens of those colonies will still be hybrids), I thought I would take the queen from one of them, and also take away the brood and eggs from that colony, and exchange it with the one having the tested Italian queen, and so let the colony from which I took the hybrid queen rear queen-cells from the Italian queen's brood and eggs. Then, after they have reared a number of Italian queen-cells, I want to give each of the old colonies having the hybrid queens an Italian queen-cell.

2. How early must I give the colony from which I want to rear Italian drones, the Italian queen? I mean the colony in which I want to put the Italian queen that I send for? Will it

be time enough if I introduce her say about the beginning of April? And will this tested queen have time enough from the beginning of April to rear drones for use by swarming-time?

IOWA.

ANSWERS.—1. You will find some difficulties, probably. Shutting in drones will make little difference if others have dark bees within a mile or less. If you succeed in having your queens mate as you desire, it will be close in-breeding, which is not considered very good. Something depends on the number of colonies to be treated. If the number is small, it may work very well. If the number is large, be prepared to meet some disappointments, and to secure a smaller crop of honey this year.

2. Very likely it will be as well not to introduce your Italian queen before April or even later. She can have plenty of drones a month later than the time she is introduced, providing the weather is warm and honey yielding. If you have two Italian queens not related, rearing queens from one and drones from the other, your success will be better, but as before said, if neighboring bee-keepers have hybrids your chances for purity are lessened.

A Question on Management.

I have 30 colonies of bees in two-story eight-frame dovetail hives. They were united last fall and wintered on the summer stands without any loss so far. I intend to run them for comb honey. I want to take away the under story and let them swarm naturally, then hive them in it on the old stand, depending upon the swarm for surplus; then unite in the fall.

1. What do you think of the plan?
2. What percent of the lower stories do you think I will get?
3. When must I take them?

WIS.

ANSWERS.—1. It may work quite satisfactorily.

2. I really don't understand what you mean. If you mean what percent of the lower stories you will have swarms to put into, that's a thing no one can tell anything about. If the season is poor enough you might have no swarms. If that isn't the right drift for your question, please ask more fully.

3. You might take them away just before, or at the beginning of, your honey harvest. In some cases there will be brood in lower stories, which can be given to other colonies which haven't brood in as many as eight frames.

Getting Bees Out of a House.

A neighbor wants me to take out several colonies of bees that have taken up their abode between the studding of his house, entering thro a crack on top the veranda. The house is nearly new and well painted. One colony stored a lot of honey in another house here, that melted one hot day, spoiling the plaster. How can I get them out without spoiling the house?

NEBRASKA.

ANSWER.—Find out about where the swarm is located by listening carefully with your ear against the wall. Make a hole in the wall in addition to the hole that the bees have been using so that one hole shall be above the other. If one hole is already near the bottom of the space occupied by the bees, make the other hole as near as possible to the top of the space, and vice versa. Put some rags very strongly saturated with carbolic acid in a smoker and blow into one of the holes till the bees run out of the other. Of course you can't get out any of the combs without cutting the wall. If the only object is to be rid of the bees without caring to save them, there may be no need to make a second hole. Just squirt a lot of carbolic acid into the hole that is there.

Closed-End vs. Loose-Hanging Frames.

In your answer to a question on page 150, in regard to closed-end frames vs. open-end frames, you say "the advantage is more than counterbalanced by the inconvenience in handling, unless I am mistaken," which it seems to me you are. I have handled bees in frame hives in a small way for a good many years, procured my first swarm in 1856, and the larger part of the time in hanging frames, but for the past 10 years I think I have had all, or nearly all, closed-end frames, and I think them very much easier to handle than the hanging frames; that they are warmer, and that bees breed up faster in them in the spring than hanging frames no one will doubt, I think, who has ever tried them.

My hives are 8 frames, but if I were to start in now I would make them 10 frame. My section of the country (southern New Hampshire) is quite 1,200 to 1,400 feet above sea-level, and we need a warm hive. My bees are wintered on the summer stands. Some years we get a fair quality of honey, and a fair amount, but in others hardly enough for the bees themselves, tho I think almost every season there is honey enough, but the weather is wrong just at the time when the bees would get a good supply if conditions were favorable.

When you try closed-end frames until you are accustomed to them I think you would hardly like to go back to hanging frames, tho perhaps propolis troubles more with you than here, but we have plenty of it.

N. H.

ANSWER.—All do not think alike about things in general, nor about hives in particular. It may be on account of the hives

themselves, and it may be on account of something else. All do not have the same management, and so what suits one may not suit another. As closed-end frames have been in use nearly as long as hanging frames, they are by no means new things, and it seems pretty clear that the majority prefer the hanging frames, considering the large number in use. It is possible that if I tried the two kinds that we have had, I might prefer the closed-end frames. I hardly think I would prefer any closed-end frame to the hanging frames I now use. I certainly know that I prefer the ones I am using to either of the kinds of closed-end frames I used, and they were among what are considered the best, and I think I gave them a fair trial. But they were so unsatisfactory that they are now untenanted. But I am quite willing to concede that others may have a different preference.

Albino Bees.

Are the albino bees equal to the Italians, as honey-gatherers? Are they any gentler?

SUBSCRIBER.

ANSWER.—As a rule, I believe that albino people, or albino animals, are supposed to be somewhat lacking in vigor, but it is possible that some albino bees may be just as vigorous as regular Italians. I think albino bees have a good reputation for gentleness.

Thin Foundation for Brood-Frames, Etc.

1. Will thin foundation do for brood-frames? If not, why?
2. Can I extract frames not wired or fastened at the bottom, and partly to the sides? I have no extractor, but will get one if those combs can be extracted. They are the large Langstroth or brood-frames.

KANSAS.

ANSWERS.—1. The chief objection to thin foundation for brood-frames is the sagging. If sufficiently supported by wires or splints, it may do very well.

2. By being careful enough, you may extract if the combs are fastened only at the top.

Comb or Extracted Honey?—Fastening Bee-Veil.

1. Which crop would you rely on one year with another if you could get 12½ cents per pound for comb honey or six cents for extracted?
2. Would you advise always using a queen-excluding honey-board when working for extracted honey?
3. Which is best, wood-slatted or plain zinc?
4. My mother cannot think of any way to keep her bee-veil fastened down at the bottom, so as to keep out the bees. Can you give any hints that will help her?
5. Which crop has the least labor connected with it, comb or extracted?

MO.

ANSWERS.—1. Comb. But in some places the other would be the best.

2. Yes, as a rule.

3. Wood-zinc. Yet it is possible you might like the plain zinc. Some excellent bee-keepers do.

4. Have a hem at the bottom through which is run a rubber cord. With a safety-pin fasten it down to the waist in front. If well stretched down when pinned, not a bee can get under.

5. Probably in most cases extracted. That is, it is less labor to run the same number of colonies for extracted than for comb. Yet it is possible they might be run in a slipshod way for comb honey with less labor than for extracted. But it would be slipshod comb honey and would command slipshod prices.

Getting Bees Into Standard Hives.

I have often intended writing you before, but if I waited a week or so some one else in the same quandry would present his case to you, and save me (and you) the trouble.

Don't tell me to get a bee-book; I got them before I had ever seen a hive of bees, except in a picture. Now I suppose you wonder what I can have to ask you, if I have any intelligence whatever. But I do not know nearly as much after having bees two summers as I imagined I did after reading a lot of bee-literature the winter of 1896-97. I bought a choice colony from a New York bee-keeper, another here, and transferred them both to Langstroth hives. It took hours—from one p.m. until after six for each one. But I did it, despite advice to get "Ole Mose Livingston," who could transfer, put in "cross-sticks," and make the bees stay, for a dollar a colony.

The first summer I was trying all sorts of experiments, dividing, rearing queens, etc. Last year I had 12 colonies, or perhaps nuclei I would better call them. Only one survived the cold snap, our below zero weather, and all my hopes are centered on that colony and one I bought but have not moved home yet. It is in a tall hive, frames 11 inches wide, and 13 inches deep, inside measure, and slanting bottom nailed on, and the four sides project three inches above the frames. What hive is it?

The colony I have here had a hybrid queen hatched July 30. They were cross, and so got a chance to build up, as I did not med-

dle with them much. Besides, they were in a Heddon hive, and the Langstroth frames were easier to handle.

I have empty, two more Heddon hives, 16 frames of good combs to each; seven Langstroth hives, combs for three of them; and another of those high hives. I want to get the bees into a Langstroth hive from the tall hive, so as to get surplus in marketable shape, but leave the combs in that hive so as to have an Italianized colony in there later and sell it to some one who does not care for "new-fangled hives." The Heddon hives will go, too, for I am not an expert to handle hives. I examine each frame, and they are too much trouble—16 closed-end frames to a hive. The surplus will be all right, over those hives, but there are only holes cut in the top edge of each frame in the other, any small box is set on top, so I want the bees out. Could I drum them all out into two of those nucleus boxes Doolittle uses, give a good queen to the queenless half, and put them back to care for brood and build up to sell, and put the others in a Langstroth hive on as many combs as they can cover with the queen, Italianize later, feeding them of course? I have some division board feeders made according to Doolittle's "Queen Rearing." I think it a good plan, but hope you can suggest something better if it is not. I have the nucleus boxes with wire sides, and was successful with them, but have lost confidence in my own plans. JOHNSTOWN, PA.

ANSWER.—Your letter interested me even before I opened the envelop, for the postmark of that ill-fated city in Pennsylvania where the flood swept so many away brought to mind the many happy days I spent in that city in the long ago. Then it's quite refreshing to find some one who has taken pains to keep her reading up to, and ahead of, her practice. It is a mistake to suppose that this department is mainly for those who have not read up in any text-book; indeed, many a question is asked by those who have had no little experience, and the advice can hardly be repeated too often that to make a success at bee-keeping one should be well read up in one or more of the text-books. Even after that there will be always plenty of room for questions.

Now between you and me, don't you think you ought to be just a little bit ashamed of yourself to let other people ask all your questions for you? What if all should do that way? But it's no time to scold now, after you've commenced asking for yourself.

I don't know the name of your tall hive.

Considering that you want to get an improved queen into the old hive at the time of making the change, your plan of dividing may do very well. But don't operate till the colony is strong, perhaps just before clover bloom. You say nothing about where you will set the two parts, and upon that much depends. If you leave the old hive on the old stand, the other will not do very well unless you give it nearly all of the driven bees. Remove the old hive to a new stand, putting the new hive on the old stand, and all the bees you put in the old hive will stay there, and for a day or two there will be an additional force coming from the old hive, for all the field-bees of the old hive will enter the new one on their return from foraging. The large number of young bees hatching out will make up the loss in good time, and the old colony will be strong enough.

Bee-Keeping in Washington—Foul Brood.

1. What part of the State of Washington is the best for bees and honey? Is any of it good? I would like to know about the east part, also on the coast.

2. What was the final decision of Messrs. McEvoy, R. L. Taylor, and others, about transferring to get rid of foul brood? Is one transferring enough, or should they be transferred twice, the last four days after the first? Should they be starved during the four days? IOWA BOY.

ANSWERS.—1. I am unable to give the desired information.

2. Nearly all agree that the bees must be thrown on empty frames of foundation the second time. The bees are not to be fed during the three or four days, the object being to get them to use up all the infected honey before there will be any larvæ to feed.

Localities for Bee-Keeping, Etc.

1. Is Virginia a good State for bee-keeping?
2. Are the Southern States better for bee-keeping than the Western?
3. Which hives are the best?
4. Do queens live as long as worker-bees? PENN.

ANSWERS.—1. Some good locations in Virginia, some not so good, but I don't know where the best are.

2. Taken as a whole, probably there isn't much difference.

3. All are not agreed on any one hive. Perhaps at present the dovetailed is the most popular.

4. Queens live from a few months to four or five years. Workers in the busy season live about six weeks. Those hatch in the fall live until some time the next spring.

Running for Extracted Honey—Preventing Swarming.

1. I want to run a few colonies of bees for extracted honey in 8-frame dovetailed hives, and prevent swarming as much as possible. The plan recommended by some is to put one or two frames of brood with the queen in the first story, filling out with fall

frames of foundation, and putting the remaining brood and bees in a second story with an excluder between. What is there to prevent the bees starting the cells above, and thus cause swarming?

2. Why won't the cells have to be cut out to make it a success? I have never seen it recommended.

3. Would it not be just as well to use no excluder but alternate the brood and combs with full sheets of foundation in both stories just before the swarming season? I have no empty combs. Which plan do you think best, and can you suggest a better one?

4. What do you think of producing extracted honey without using excluders? Are not a good many doing that now? CONN.

ANSWERS.—1. The great amount of empty room in the story that contains the queen is enough to prevent the desire to swarm.

2. There is no mention of cutting out cells, because none are expected.

3. Your plan is not so sure to prevent swarming, and the frames of foundation will not be so well built out. A frame of foundation between two full combs is often made thin, while the cells of the old combs are unduly lengthened. The other plan has been tried and approved.

4. Probably no one who has tried the two ways thinks it better to use no excluder. With the excluder you never need put brood in the extractor. Read the article by C. Davenport, on page 179. A good many put brood in the extractor, and a good many have thus a poorer quality of honey.

Combs Left with Honey in Them.

What had I best do with some combs of honey that I have? I left 20 colonies of bees on the summer stands last fall, after packing the upper stories with forest leaves; but after the extreme cold weather that we had for 20 days (the thermometer hardly ever registering above zero, and at one time 48 degrees below zero) there was not a live bee in the whole 20 colonies. Now, after the weather gets warm enough for bees to fly freely, would it do to let my other bees—some 51 colonies—carry out the honey from the first-mentioned hives, and save the combs, and after cleaning hives and combs, use them for putting swarms on, the coming season?

How would it do to clean up the hives and combs as well as I can, and put swarms right on the combs with honey in them, putting sections on swarms right away, or soon after putting the swarms into the hives? WISCONSIN.

ANSWER.—Either plan you mention will work all right. Only, if you allow the bees to rob out the honey, be sure not to move any of the hives they are robbing until several days after all the honey is cleaned out. There is danger that worms may trouble the combs before swarming-time, so perhaps the best thing is to put each empty hive under one of your good colonies till swarming-time. That will make them safe from worms, and it will also insure their being cleaned up well.

Brood-Chamber Crowded with Honey.

I have just bought 3 colonies in 8-frame Langstroth hives. They seem to contain a good deal of honey, and I should think that by and by there will not be enough room for brood. They weigh about 50 pounds each. I am a beginner, and have no extractor as yet. Would it do, when the combs now empty are getting full of brood, to take the two outside combs of honey and put them in the middle, and put on a super? Would the bees take the honey up and store it in the sections? We are earlier here than you are; I had a swarm out on May 12, last year. B. C.

ANSWER.—You will probably find that the bees will use up more of that honey in brood-rearing than you suppose. You will hardly find it satisfactory to try to get the honey carried into sections. It's a good thing to have some combs of sealed honey on hand in case of need.

Keeping Bees in a Garret.

I wish to ask you in regard to putting a colony of bees in the garret of a house. I want to put them in the north end so they will face the north. Will that do, or would it be better to face the south? Give directions how to build such a hive. A neighbor wanted me to construct it for him in his house. The house is heated with hot air, and can be regulated. ILLINOIS.

ANSWER.—It is generally considered that bees will do better facing south than north. A hive for a garret may be built the same as a hive for out doors, the special point of difference being that particular pains must be taken to have a passage-way from the entrance of the hive to the outside by means of a passage-way that shall allow no bee to get out into the garret.

Brood-Combs with Candied Honey.

What can I do with candied honey in the brood-frames? Will the bees remove it, or shall I destroy the combs? KANSAS.

ANSWER.—I think I would try the plan of M. M. Baldrige. Spray the combs with warm water and give to the bees, repeating the spraying as often as necessary.

GEORGE W. YORK, Editor.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY,

118 Michigan St., Chicago, Ill.

ONE DOLLAR A YEAR.

SAMPLE COPY FREE.

[Entered at the Post-Office at Chicago as Second-Class Mail Matter.]

United States Bee-Keepers' Association.

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee \$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., E. Whitcomb; Vice-Pres., C. A. Hatch; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GEN'L MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

Place and Date of Next Meeting:

Philadelphia, Pa., September 5, 6 and 7, 1899. Every bee-keeper is invited.

VOL. 39.

APRIL 13, 1899.

NO. 15.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

THE DREAMER.

Let the dreamer lie at ease
And gaze at the bright blue sky,
Lulled by the murmuring bees,
While the summer winds go by,
Tho' its skies be cold and gray,
Be this thy heart's content—
That thine is the sweeter day
In useful labor spent.—Farm Journal.

Honey Leaflets as Honey-Sellers.—Editor Root, of Gleanings, finds a number of his readers report that honey leaflets are not a success as honey-sellers. He thinks the trouble is that they are gotten up in too cheap a form; that something more expensively and attractively gotten up might do better, and asks for opinions.

We think the trouble has been that nearly all the leaflets put out so far have been too large—there is too much to read. Busy people haven't time to wade thru so much. Perhaps a single leaf printed on both sides in clear type like this would be better. Say a leaf of paper about 5x8 inches. It might have two or three small pictures on it.

But, after all, much depends upon the honey itself. If it is of as good quality as it ought to be, and prospective customers get a good taste of it, they will buy if they really want any honey, and if the price is right.

Many people do not care for honey—wouldn't eat it if it were on the table every meal. But there are enough people

who do like honey to use every pound that can be produced, if only it could be brought to their attention. How to do that thing is one of the great questions yet to be satisfactorily solved. If any of our readers know *how*, and wish to help, our columns are open.

LATER.—In Gleanings for April 1, we find the following in reference to the use of honey leaflets, from Mr. Dan White, who seems to know *how* to use them:

Now, then, Mr. Editor, you want our views. Should the leaflet be more expensive? I might suggest one verse or a few lines added for the *express* purpose of cutting out and pasting in our hats. I should want it to read something like this:

"Don't waste these leaflets, throwing them on porches, and scattering them around promiscuously.

"Don't use these leaflets if your honey is not of good quality and *thoroly* ripened before it was extracted.

"Don't forget, when you do make a sale of *good* honey, to hand the customers a leaflet.

"Don't forget to tell them that it will teach them how to warm up candied honey; it will educate them quite a little.

"Don't forget that very *few* are educated about honey and bees.

"Don't forget that half the people hardly know what honey is. They should and will if we do our part well. Those leaflets will help do the talking.

"Don't forget to leave a sample of honey when you call from house to house.

"Don't forget to leave the leaflet and your name and address, because, after they eat the *good* honey they will read the leaflet and then say, I *must* get some of that honey."

Don't you see we almost compel them to read those leaflets, and also buy our honey? Don't forget to stay at home, too, if your honey happens to be a little off—so much so that your own family don't like it. Don't forget that poor honey sells poorly, just the same as any other poor thing. Don't forget those leaflets are all right if you know how to use them rightly. Don't forget to take off your hat every few days and read these *don't's*. Don't forget that, if the leaflets are all right in one place, they *must* be so in other places.

Order Bee-Supplies Early is the usual annual advice to bee-keepers at this season of the year. Experienced honey-producers hardly need be so reminded, but the beginners, or those of limited experience, perhaps should be advised to have on hand, in ample time for use, all supplies that will likely be required during the honey season. Be prepared for whatever comes, whether it be a large crop or a failure.

Howell's Scripture Honey-Cake.—The whites of eight eggs well beaten, Job. 6, 6; one-half cup of butter, Gen. 18, 8; one cup of honey, Gen. 43, 11; one-half cup of sweet milk, Gen. 18, 8; flour to make a stiff batter, Leviticus 2, 2; spices and almonds to suit taste, Gen. 43, 11, and a little leaven, 1 Cor. 5, 6. Bake it to-day, Exodus, 16, 23.

Great Britain's Honey Imports during 1898 amounted to about \$120,000. So reports the British Bee Journal.

Smart Bees in Texas.—The Evanston (Ill.) Index contained an item in regard to some "smart bees" in Texas. Mrs. N. L. Stow, vice-president of the Chicago Bee-Keepers' Association, saw the item and kindly handed it to us. It reads as follows:

"The busy bee has long had a reputation for industry, but I always considered it rather conservative until I ran across the up-to-date variety that does business in the Fort Davis region of west Texas." So spoke a former journalist, now a railroad man. "They have some of the finest honey in the world out there, and its delicate flavor is due to the blossom of a shrub that grows profusely on the mountain sides. The trouble is, however, that the flowering season

of the bush is brief, at a given altitude, and the bees have to follow their favorite food higher and higher as the season advances. Now, you know the bee makes a 'bee-line' for the hive as soon as she has soaked her feet in the liquid sugar of the flower.

"Well, the west Texas bee evidently found it very inconvenient to climb all the way down to the valley with each load of honey, and some smart bee struck upon a plan as simple as it was unique. It is generally known that the self-same shrub that gives honey to the bees produces a succulent root, upon which as big and rocky-looking a lizard as you ever saw feeds and fattens. This creature, called a 'yollo' by the Indians, is 14 inches long, and is too lazy to get out of its own way. The yollo's back bristles with points, and he is terrible to behold, yet to the bee he is only a God-send, and without the least fear a swarm will proceed to establish its comb between the points of the yollo's pachydermatous back, and without ado fill in the honey. The beast, of course, following the food-plant, will keep the hive always within easy walking distance, and in the fall, when the season is over, the bees swarm back into the lower level, while their diminutive pack-mules wind down the mountain paths to the valley, where the honey is quickly transferred to its winter quarters in the bees' trees or the ranchman's hive."

Perhaps some of our readers in the locality referred to can tell us something further about this. More than likely it is "only a bee-story."

The Philadelphia Bee-Keepers' Association is thus spoken of by the Philadelphia Public Ledger:

There are many associations of bee-keepers in America and Canada, but of them all that of the Philadelphia bee-keepers is the oldest, and in its day has been the most prominent and influential. Its origin and continuance, and the good work done in and thru it, have all been due to the efforts of the president, Dr. Harry Townsend and his good wife, both of whom are devoted friends of the honey-bee, and thru all the years have had faith that some day its economic importance would be recognized, and farmers, villagers, and even city people, would come to understand that with its aid a luxury could be added to the table, and dimes to the pocketbook, and from the otherwise wasted sweets in the flowers of field, forest and garden.

As the United States Bee-Keepers' Association will hold its next annual meeting in Philadelphia, its members will have the privilege of meeting the members of the Philadelphia association. We wonder if it really is older than the National society.

Tin Cans vs. Barrels for Honey. We hope that tin cans will be considered more favorably this year by those who have been using barrels heretofore for holding extracted honey. Cans may be a trifle more expensive, but they are ever so much more convenient for handling, and for reliquefying the honey. Then they seldom "spring a leak" as do the barrels. Neither do cans soak up a lot of honey, and thus cause waste and loss to the shipper or buyer. There are so many evident advantages possess by cans over barrels that all need not be enumerated here. We trust that the leaky, bulky, cumbersome honey-barrel may soon be a thing of the past.

York's Honey Almanac is a neat little 32-page pamphlet especially gotten up with a view to create a demand for honey among should-be consumers. Aside from the Almanac pages, the forepart of the pamphlet was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample for a stamp; 25 copies for 40 cents; 50 for 60 cents; 100 for \$1.00; 250 for \$2.25; 500 for \$4.00. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

The Premium offered on page 236 is well worth working for. Look at it.

HON. EUGENE SECOR, of Winnebago Co., Iowa, wrote us April 5:

"Two days of spring. Bees are still in the dark. Considerable loss is reported."

MR. WM. FRICKER, of Hampshire Co., Mass., when sending a new subscriber for the Bee Journal, March 23, wrote:

"I have taken the American Bee Journal over a year, and I am more than satisfied. No bee-keeper should be without it."

THE FARM JOURNAL is the boiled-down, hit-the-nail-on-the-head paper, cut to fit the wide-awake farmer and villager. We give the Farm Journal for the balance of 1899 and all of 1900, 1901, 1902 and 1903, nearly five years, as a premium to every one of our subscribers who will accept the offer on page 222.

MR. G. M. DOOLITTLE, of Onondaga Co., N. Y., wrote us April 3:

"Snow and cold here with no let up for spring yet. Bees out-doors are in bad shape, with many dead, as they have had no good chance for a flight since last November, or nearly 4½ months."

DR. C. C. MILLER is not only a prominent bee-keeper, and a leading writer on bees, but he is also a well-known worker in the Presbyterian church. He bears the distinction of being the only layman in the State of Illinois who is chairman of any of the many committees of the synod which comprises the Presbyterian churches of the State. Sometimes we are inclined to think that it is the Methodist blood in him that helps to make him a good Presbyterian. You know it is said that "blood tells."

MR. O. O. POPPLETON, of Dade Co., Fla., wrote us March 28:

"My honey season is just coming on. As I wrote you a short time ago, our bees are not in their usual strong condition for the time of year, and altho the saw palmetto promises an unusually large flow of honey, the lack of strong colonies will prevent my getting a full crop. Other bee-keepers up and down the coast, whose fields were not so badly fire-swept as mine were last spring, tell me their bees are in their usual condition."

MR. C. A. HATCH, of Richland Co., Wis., vice-president of the United States Bee-Keepers' Association, wrote us April 6:

FRIEND YORK:—According to present indications there is to be no very serious loss of bees in our part of Wisconsin. I have talked with four or five bee-keepers representing an ownership of over 600 colonies, and only one reports serious loss, and this lot were wintered out-of-doors protected by straw packing only. Of course, bees are in the cellar yet, and putting-out time may change things somewhat, but I think not much.

"It is too early to say much about the honey prospect, but I can say this much, white clover does not appear to be injured. I hope for a good honey season, and a prosperous year."

THE FEARFUL TRAVELER. Dr. Peiro has traveled a good deal, and makes the following observations:

"It is almost pathetic to note, in traveling, the fear some display at their surroundings. Not from danger of accidents, but dread of the evils that may befall them from contact with their fellow travelers.

"From childhood they have been admonished regarding the subtlety of strangers that the unfortunate credulous are at once on guard, and the defensive, lest every hand but their own be raised against them. The anxiety they display on this score is manifested by the ludicrous efforts

they make for the safe keeping of their treasures. They not only frequently glance in the direction of their stored valuables, but inadvertently clasp their hands over them for greater assurance, thus revealing their secret to such as might annoy them. This constant fear greatly mars the pleasures of traveling. The only class likely to come to grief is the ignorant and vainglorious, anxious to display their 'Smart Aleck'-ism to all who seem to cater to their conceit. These fools - they are generally from 18 to 24 - deserve the punishment they so glaringly invite.

"The better way is to modestly attend to one's legitimate business, and conclude that our fellow travelers are as reasonable, civil and as honest as ourselves. This principle will secure for us due respect and avoid disappointments."

"DR. PEIRO."

To Secure the Whitest Sections, Mr. Shaver, of Canada, allows no sections to be sealed over old brood-combs. Colonies with old combs are allowed to build combs in sections and fill them, but, as the capping process is begun, the super is transferred to a colony of the current year. - Bee-Keepers' Review.

Keeping Bees Good-Natured is considered by T. F. Bingham, in the Bee-Keepers' Review, and the moral of his discourse is that if we would get along in towns without having complaints from neighbors as to cross bees, we should keep a cloud of smoke in the apiary when working with them. A good bit in that. It is also quite possible that Mr. Bingham had in mind that if more care were taken in this respect there would be more Bingham smokers in use, and there was nothing wicked in the thought if he did think so.

The Secret of Successful Honey-Production, according to Messrs. Aikin and Doolittle, in the Progressive Bee-Keeper, lies in so manipulating colonies as to have the maximum number of bees on hand ready for the harvest, and those bees without any desire to swarm. To prevent swarming, Doolittle says cage the queen for 10 days just before harvest, then cut out all queen-cells, cage the queen, or one just commencing to lay in her place, in a cage with a stopper of candy that will take the bees about two days to eat thru, and swarming is done for six weeks, and for the whole season unless the honey-flow is long drawn out.

Latest Development in Weed Foundation. A series of illustrations in Gleanings show thicknesses of walls and bases in natural comb and in different kinds of foundation, running from five to 13 feet to the pound. It seems to be a question that has not been fully settled in the minds of all whether it is better to have extra wax in the base or in the incipient side-walls, or whether the bees would thin either or both. The latest effort of Mr. Weed is to produce foundation with a very thin base, with a side-wall not very deep

but containing considerable wax. The experiments of Hon. R. L. Taylor showed a thinner base in Given foundation than in others, notwithstanding the fact that rolls would make a more regular and a nicer-looking article. Editor Root says that "experiments show that we can stick as much wax as we like in the walls, for it will be thinned down; but we must be careful about getting too much in the bases; for while the bees may thin it there, they rarely do; and the excess of wax, therefore, in the bases is simply so much waste product, and who pays for it? The bee-keeper, and not the supply-dealer." At present the new product is made with plates, in sheets large enough to fill a section, the thickness being about 1/4-inch.

Spraying Fruit-Trees.—J. W. Rouse says that spraying trees when in bloom shows ignorance on the part of the sprayers. The time to spray depends on the object of the spraying. For fungus, before bloom. For codling-moth, after the bloom has fallen, as the moth does not deposit her eggs until the fruit is set. For information as to spraying, send to Cornell University, Ithaca, N. Y., for Bulletin No. 101 (The Spraying of Trees), also Bulletin No. 86 (Spraying of Orchards), both being sent free, as also Farmers' Bulletin No. 7, sent out by U. S. Department of Agriculture, Washington, D. C. The best of all is the Spray Calendar, issued in 1895 by Cornell University Agricultural Station. —Gleanings.

Bee-Keeping No Sinecure in Cuba.—A. W. Osburn's son warns adventurers not to be too rash in rushing into a strange country to make a fortune. Money, big money, can be made at bee-keeping in Cuba, but it takes work, big work. To produce a crop of honey requires 365 days' work in the year. "The tropical sun shines and the flowers bloom the year round." Beginning with March, for an apiary of 500 or 600 colonies, 125 or 150 queens must be reared, got to laying, and colonies must be built up. By May swarming is in full blast, no time for a nap between swarms, and for four months the wax-worm furnishes much employment. Then when the harvest begins to come in, when the 500 or 600 colonies get limbered up and bring in 2,500 or 3,000 pounds in a day, "you have to step around as if you had coals of fire in your shoe." The thought of taking in \$125 a day occasionally, is hinted at as no slight offset. —Gleanings.

Boiling Foul-Broody Honey.—J. H. Martin comes in as a pacificator in Gleanings, with the belief that those who hold such diverse views as to the time of boiling necessary to kill foul-brood spores may all be right. He thinks the boiling acts in strata, the lower stratum boiling first, and so on to the top. A small amount will be boiling thruout in a short time, but not so a larger quantity. He advises, "boil a gallon in a large boiler 10 minutes, 20 gallons an hour, 50 gallons three hours." Prof. Hodge, in the same journal, calls attention to the much greater difficulty of destroying the vitality of spores, advising at least 15 minutes boiling with thro stirring on three successive days. The expectation is that by the time of the third boiling all the spores may have vegetated, and as bacilli 15 minutes will be enough to kill them. T. W. Cowan says: "The spores also possess the power of enduring adverse influences of various kinds without injury to their vitality, so far as germinating is concerned, even if subjected to influences fatal to bacilli themselves. The latter are destroyed at the temperature of boiling water, while the spore apparently suffers no damage at that temperature."

SWEET CLOVER

And Several Other Clover Seeds.

We have made arrangements so that we can furnish Seed of several of the Clovers by freight or express, at the following prices, cash with the order:

| | 5lb | 10lb | 25lb | 50lb |
|-----------------------|-----|--------|--------|--------|
| Sweet Clover mellilot | 60c | \$1.00 | \$2.25 | \$4.00 |
| Alsike Clover | 70c | 1.25 | 3.00 | 5.75 |
| White Clover | 80c | 1.40 | 3.00 | 5.00 |
| Alfalfa Clover | 60c | 1.20 | 2.75 | 5.00 |
| Crimson Clover | 55c | .90 | 2.00 | 3.50 |

Prices subject to market changes. Add 25 cents to your order, for cartage, if wanted by freight. Your orders are solicited.

GEORGE W. YORK & CO.

118 Michigan Street, CHICAGO, ILL.

Pure-Bred Poultry

than it does common stock, and it pays tenfold better. Send stamp at once for Illustrated Catalog and Poultry-Book.

DREXEL POULTRY YARDS CO.

361 Fifty-third Avenue, DREXEL, ILL.

It Costs No More

TO FEED, RAISE AND HOUSE GOOD

TWO WAGONS AT ONE PRICE.

It is a matter of great convenience and a saving of labor for a farmer to have a low, handy wagon. They save more than half the labor of loading in hauling manure, hay, grain, corn-fodder, wood, stones, etc. The man who already has a wagon may have one of these low

handy wagons at the small additional cost for a set of wheels. These Electric Steel Wheels, with either direct or stagger spokes, with broad-faced tire, are made to fit any axle. You can convert your old wagon to a low, handy wagon in a few moments. You thus virtually have two wagons at one price. Write to the Electric Wheel Co., Box 16, Quincy, Illinois, for their catalogue, which fully explains about these and their Electric Handy Wagons, Electric Feed Cookers, etc.

Root's Column

No=Gob Foundation.

We Have it at Last.

It has been proven that wax in the base of ordinary foundation is not utilized by the bees, but is left there practically as it leaves the mill; and the result is, when drawn out into comb, the so-called gob, or fishbone, in comb honey.

Our New Thin-Base FOUNDATION

is exactly what its name indicates— foundation with a base as thin as natural comb, with heavy deep walls.

Fig. 7, herewith shown in cross-section from an actual photo, represents the new thin-base heavy-walled foundation running about 10 feet to the pound.

Fig. 13 represents the ordinary thin foundation with heavy base and scarcely any wall, about 10 feet; the heavy base, without modification, going right into the comb honey with very little change, and forming fishbone.

We have so far only small dies, and cannot afford to sell this product for less than \$1.00 a pound. Next year, perhaps, we shall have larger dies, and will make a corresponding reduction in price.

Seven or eight pieces, large enough to fill 4 1/2 sections, 15 cents, postpaid; 24 pieces, prepaid, 40 cents.

The A. I. Root Company
MEDINA, OHIO.

GENERAL ITEMS

Bees Came Thru All Right.

The bees have come thru so far all right, but it looks blue for them this morning—April 3—with the ground all covered with snow. I hope this will be a favorable season for them. They are all (some 80 colonies) in the home yard in town. I am not able to go to the country to have an apiary, as I will be 72 years old May 12. I never employ any help, but do all the necessary work myself. Success to the Bee Journal.

D. C. McLEOD.

Christian Co., Ill., April 3.

Organizing in Utah.

We have formed a bee-keepers' organization here within the last month, known as the Uinta Bee-Keepers' Association, starting in with about 25 members. We hope to start other associations, and work in harmony in every respect. We have sent a petition to our congressman in regard to the pure food law. I am pleased with the Bee Journal.

* I have not lost one colony out of 96. All are doing well, and have plenty of brood and young bees. G. W. VANGUNDY.

Uinta Co., Utah, March 12.

Poor Season Last Year.

The bees last year did very poorly. I got only about 1,000 pounds of comb honey from 150 colonies. So far they have wintered fairly well. J. N. SCHUMACHER.

Platte Co., Mo., March 17.

Bees Wintered Nicely.

My bees wintered nicely on the summer stands. I did not lose any. They gathered considerable honey from the plum and peach bloom, but everything is too dry for any more until it rains. Crops look bad—wheat and oats drying up. Our corn was bitten down by frost March 28, but is coming out again. D. F. MARRS.

McLennan Co., Tex., April 3.

Backward Spring.

The spring is very backward. Snow has fallen to the depth of over eight inches the last three days. There is heavy loss of bees thruout this section.

E. T. FLANAGAN.

St. Clair Co., Ill., March 29.

Over Half the Bees Dead.

Over 50 percent of my bees will be winter-killed, and the balance in very bad condition, owing to the severe winter. They were on the summer stands. C. BECKER.

Pleasant Plains, Ill., March 28.

Bees Not Wintering Well.

Bees are not wintering well. Those in the cellar are spotting hives badly. It has been such bad weather that they could not be taken out yet. The ground was covered with snow last night. GEO. L. FERRIS.

Cayuga Co., N. Y., March 31.

"Adel" Bees are "Superior."

EDITOR YORK:—Kindly permit me to correct one statement Dr. Miller made when he replied to the question, "What are Adel bees?" If my memory serves me correctly, he made this reply: "Any strain of Italian bees can be called Adel," or something very much like this.

The bees that I call Adels (properly pronounced *Ad'el*) were bred up in my apiary from the gray Carniolans, which came

Doolittle's Book Free!

Every Bee-Keeper should have

SCIENTIFIC QUEEN-REARING.

YOU CERTAINLY will have it if you desire to know how to have queens fertilized in upper stories while the old queen is still laying below; how you may safely introduce any queen at any time of the year when bees can fly; all about the different races of bees; all about shipping

queens, queen-cages, candy for queen-cages, etc.; all about forming nuclei, multiplying or uniting bees, or weak colonies, etc.; or, in fact, everything about the queen-business which you may want to know. The price of the book is \$1.00, being bound in cloth, gold-lettered.

We want 1,000 New Subscribers

Between Now and June 1,

And we would like to have our regular subscribers help us in this work. In order that all who may want a copy of Doolittle's "SCIENTIFIC QUEEN-REARING" may earn it very easily, and at the same time aid in swelling the Bee Journal's list of subscribers, we wish to make the following **Liberal Offers**—only to our present subscribers:

Offer No. 1. We mail the book for \$1.00, or club it with the Bee Journal for one year—both for \$1.75.

Offer No. 2. Send us **Three New Subscribers** to the Bee Journal for the balance of the year, at **60 cents each**, and we will mail you a copy of the book free as a premium.

Offer No. 3. Or, send us **two new subscribers** to the Bee Journal for the balance of this year at **60 cents each**, and **40 cents additional**, making \$1.00 in all, and we will mail you the book.

Offer No. 4. Or, send us **one new subscriber** to the Bee Journal for the balance of this year at **60 cents**, and **65 cents additional**, making \$1.25 in all, and we will mail you the book.

Now, the sooner the new names are sent in the more copies of the Bee Journal they will get for their 60 cents, and if sent before April 1, each will be certain of getting the Bee Journal for **nine months**, or about 40 copies.

Remember, that **only our present subscribers** can take advantage of the last three offers above.

Now, let everybody go to work, and help roll up the 1,000 new subscribers.

Address,

GEORGE W. YORK & CO.

118 Mich. St., Chicago, Ill.

direct from Carniola. Frank Benton, who spent many years in Carniola, says he never saw an apiary of all steel-gray bees in that country. In all apiaries there are more or less yellow-banded bees. The native bee-keepers consider the yellow-banded superior to the gray bees, and call them "Adels." Adel signifies superior.

Bees are wintering well, tho March has been the worst month of the year; no warm weather, but plenty of small snow-storms. HENRY ALLEY.

Essex Co., Mass.

[If Adel simply means "superior," then of course Dr. Miller was right if he said that "any strain of Italians can be called Adel," provided they are excellent bees. No one has the sole right to the words "Adel" or "superior," any more than to the words "simplicity" or "perfection," as we understand it.

Several of our readers, during the past few years, have enquired as to the meaning of "Adel bees." It seems to us if we were to designate any particular variety of bees, we would call them by some name that would be self-explanatory—some word that could be found in any common dictionary. —EDITOR.]

Wintered Well in a Bee-Cellar.

I have 112 colonies in a bee cellar 15x33 feet. They are wintering nicely. Last season I got one-fourth crop of honey. I hope this year they will do better. Success to the American Bee Journal.

E. R. WRIGHT.

Scott Co., Iowa, April 4.

Wintered All Right.

My bees came thru the winter all right, tho a little short of stores, but with plenty of bees.

I find lots of hints in the "Old Reliable" that come in handy. I wish you success.

J. BRIMMAGE.

British Columbia, March 24.

An Old Bee-Keeper's Experience.

I have been reading the "Old Reliable" for two years, and I could hardly keep bees without it now. I have kept bees 25 years, but am a farmer, and, until late years, I was at the head of a dairy and stock farm, but as age came on I had to turn the care of the farm into younger hands, which is run under the name of F. Hall & Son. But I cling to the bees and the garden. I never wintered more than 21 colonies. I used to keep them in box hives and wintered them buried in the ground, sometimes fairly well and other times not so well. But the soft winter of 1877-78 cleaned out my bees. The last 15 or 20 years I have just put them into the cellar, which I will describe.

All of it has a well-mortared wall, and the exposed sides have a double wall, all cemented on the bottom. The bee-cellar is 8x14 feet, partitioned off by a single brick wall. A window on one side has a wire screen on the outside and a hanging glass window on the inside. In the winter I just bank up that window with straw, and in mild weather I open the inside window and the straw will let in enough air. This cellar just nicely holds 21 hives without tiering up.

Usually about Nov 10 I put in the bees, and see that they have plenty of air from the bottom, and I aim to put in none but good colonies, but I can't always stick to that rule. I put them on planks on old bee-hives. I don't have any trouble with mice. I just fix the door so they can't gnaw, and keep it shut.

I usually take the bees out about April 1. I never have any mould in the hives, and if they were all in good shape in the fall I don't expect to lose a single colony. There

has not been a day this winter that I, being a little deaf, could hear them at all.

In September, 1877, I took away all the queens, which were black, and two days after I had an expert bee-man introduce fertile Italians, without a single failure in 21 colonies.

I have been greatly helped by my acquaintance with good bee-keepers, particularly the late B. Taylor and D. H. Whitmore, of Minnesota, and S. T. Pettitt, of Canada; and by reading the articles written by the great bee-men in the American Bee Journal.

I read much of robbing of bees, and of wax-moths, but I never have any trouble with a colony that is worth having. Often there are moths in the honey after it is taken off, and I always put out in the apary anything that I want cleaned off. When I "take up" hives in the fall I extract the honey from the frames and put them among the bees, and when they are well cleaned off I put the frames back into the hives, and leave them there till needed again, and I find that by that time the old pollen will have shrunk so that the bees can pull it out.

FRANCIS HALL,
Fillmore Co., Minn., March 11.

Very Late Spring.

I have 24 colonies of bees now. The spring is very late here, with 15 inches of snow on the ground, and below zero last night.

C. F. GREENING,
Mower Co., Minn., March 27.

An Experience with Bees.

About 15 years ago I purchast three colonies of bees for \$10. At that time I knew little about bees.

My bees are situated to the south and west of my residence. The hives all face east, and are in rows six feet apart and three feet apart in the row. They are all, or nearly all, in chaff hives. The chaff hive, like all hives, has some good points, and some people seem to think a great many poor ones. I talk with a man who said he didn't like the chaff hives because the bees wouldn't start in the morning until the sun warmed them up. If he had been at my place last summer, some mornings, before sunrise, he would have thought that my bees didn't wait for the sun. Perhaps his bees don't work before sunrise, but mine do.

The spring of 1897 found me with 23 colonies, which I increast to 41, and harvested about 1,500 well-filled sections. My best colony gave me 100 complete sections. Passing the winter of 1897-98 without loss, I increast the 41 colonies the following summer to 58, and secured 1,200 pounds of honey, working exclusively for comb, which sold in my home market at 10 and 12 cents per pound. My honey is all gone, and I could have sold more if I had had it.

I have tried a great many times to get subscribers for the American Bee Journal, but of no avail, as the people had all sorts of excuses, some thinking they know more (about bees) than all the bee-editors and their correspondents put together. One young man, in particular, bought a number of colonies last summer. I tried to have him take the Bee Journal but he did not, and now he has just one colony alive; but he has the bee-fever for sure, for he bought six more at \$3.20 per colony, and a lot of old hives at 50 or 60 cents apiece, that were just fit for kindling. My bees were out the 7th, and seemed strong and all right. I have always been successful in wintering bees in chaff hives on the summer stands, but I never could succeed in the prevention of swarming.

My inside hive is the regular 8-frame dovetail, while the outside is made of ship-lap siding, the greatest objection being the cost.

CLYDE CADY,
Jackson Co., Mich., March 20.

BEE=BOOKS

SENT POSTPAID BY

George W. York & Co. 118 Mich. St. Chicago.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman. It is nicely illustrated, contains 160 pages, beautifully printed in the highest style of the art, and bound in cloth, gold-lettered. Price, in cloth, 75 cents; in paper, 50 cents.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.25.

Bee-Keepers' Guide, or Manual of the Apiary, by Prof. A. J. Cook, of the Michigan Agricultural College.—This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 460 pages, bound in cloth and fully illustrated. Price, \$1.25.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00.

A B C of Bee-Culture, by A. I. Root.—A cyclo-pædia of 400 pages, describing everything pertaining to the care of the honey-bees. Contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and entertaining writer. You should read his book; 90 pages, bound in paper, and illustrated. Price, 50 cents.

Rational Bee-Keeping, by Dr. John Dzierzon. This is a translation of his latest German book on bee-culture. It has 350 pages, bound in paper covers, \$1.00.

Bienen-Kultur, by Thos. G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey." 100-page pamphlet. Price, 25 cents.

Bienenzucht und Honiggewinnung, nach der neuesten methode German by J. F. Eggers. This book gives the latest and most approved methods of bee-keeping in an easy, comprehensive style, with illustrations to suit the subject. 50 pages, board cover. Price, 50 cents.

Bee-Keeping for Beginners, by Dr. J. P. B. Brown, of Georgia. A practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 100 pages, bound in paper. Price, 50 cts.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 pages, illustrated. Price, 25 cents.

Apiary Register, by Thomas G. Newman. Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25.

Dr. Howard's Book on Foul Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cents.

Winter Problem in Bee-Keeping, by G. R. Pierce.—Result of 25 years' experience. 30 cts.

Foul Brood Treatment, by Prof. F. R. Cheshire.—Its Cause and Prevention. Price, 10 cts.

Foul Brood, by A. R. Kolnke.—Origin, Development and Cure. Price, 10 cents.

Capons and Caponizing, by Dr. Sawyer, Fanny Field, and others.—Illustrated. All about caponizing fowls, and thus how to make the most money in poultry-raising. 64 pages. Price, 20c.

Our Poultry Doctor, or Health in the Poultry Yard and How to Cure Sick Fowls, by Fanny Field.—Everything about Poultry Diseases and their Cure. 64 pages. Price, 20 cents.

Poultry for Market and Poultry for Profit, by Fanny Field.—Tells everything about Poultry Business. 64 pages. Price, 20 cents.

York's Honey Almanac is a neat little 24-page pamphlet especially gotten up with a view to creating a demand for honey. A very effective helper in working up a home market for honey. Prices: A sample for a stamp; 25 copies for 40c; 50 for 60c; 100 for \$1.00; 250 for \$2.25; 500 for \$4.00. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, April 8.—Choice grades of white, 12⁰⁰13c; travel-stained and light amber, 10⁰⁰11c; buckwheat and dark, 7⁰⁰8c. Extracted, white, 7⁰⁰8c; amber, 6⁰⁰7c; dark amber, 5⁰⁰6c. Beeswax, 26c.

Stocks of white comb honey are about exhausted, and this is as it should be if a market is to be had for the expected large flow of nectar from the season of 1899. R. A. BURNETT & Co.

DETROIT, March 9.—Fancy white comb scarce and higher and we now quote it 13⁰⁰14c; No. 1, 12⁰⁰13c; fancy dark and amber, 10⁰⁰11c. There is considerable poor honey in the commission houses which is offered at 8⁰⁰9c. Extracted, white, 6¹²007c; dark, 5⁰⁰6c. Beeswax, 25⁰⁰26¹²2c. M. H. HUNT.

NEW YORK, March 8.—Fancy white, 12c; No. 1 white, 10⁰⁰11c; amber, 9c; buckwheat and dark, 6⁰⁰7c. Comb honey is pretty well cleaned up now and we expect to dispose of the balance of our stock during this month. Excepting California there is not much stock of extracted on our market. Demand is fair at unchanged quotations. Beeswax, 27⁰⁰28c. HILDRETH BROS. & SEGELKEN.

SAN FRANCISCO, March 15.—White comb, 10⁰⁰10¹²2c; amber, 7¹²009c. Extracted, white, 7¹²007c; light amber, 6¹²007c. Beeswax, 24⁰⁰26c.

Present slim stocks admit of only a light jobbing business being transacted, with values much the same as previously noted. The coming crop is likely to be small. The bees are now being fed in a large portion of Southern California, and many are reported to have already died.

BOSTON, April 1.—Fancy white, 13c; A No. 1, 12⁰⁰12¹²2c; No. 1, 11⁰⁰12c; No. 2, 9⁰⁰10c; demand fair; no call for dark. Extracted, supply very light, good demand. White in 60-pound cans, 7¹²2c; light amber in barrels, 7c. Beeswax, very light stock, good demand, 28c. BLAKE, SCOTT & LEE.

KANSAS CITY, April 6. Fancy white comb honey continues in good demand at 13¹²0014c; choice white at 12¹²0013c; dark, 10¹²0011¹²2c. Extracted scarce at 6¹²2c. PEYCKE BROS.

CLEVELAND, March 9.—Fancy white, 13⁰⁰14c; No. 1 white, 12⁰⁰13c; A No. 1 amber, 10⁰⁰11c; No. 2 amber, 9⁰⁰10c; buckwheat, 8c. Extracted, white, 7c; amber, 6c; buckwheat, 5c. A. B. WILLIAMS & Co.

BUFFALO, April 1.—Little or no strictly fancy one-pound comb honey here. It would sell well at about 11⁰⁰12c. Few lots of common, dark, etc., arriving, and sell at 7⁰⁰8c, mostly; some very poor at 6c. There is no extracted here; worth from 4¹²005¹²2c; extra fancy, 6c. Fancy pure beeswax, 3⁰⁰32c; poor, 25⁰⁰28c. BATTERSON & Co.

OMAHA, April 1.—Fancy white quotable at 13⁰⁰13¹²2c; choice, 12⁰⁰12¹²2c. Extracted, 6¹²2c. Quotations are practically nominal, as there is no stock left now in receivers' hands, and dealers have also but very little left. There will not be a pound of any kind of honey carried over in this market. PEYCKE BROS.

MILWAUKEE, March 2.—Fancy 1-lb. sections, 13⁰⁰14c; A No. 1, 12⁰⁰12¹²2c; No. 1, 11⁰⁰12c; dark or amber of old, 7⁰⁰10c. Extracted, in barrels or kegs, white, 7⁰⁰7¹²2c; dark, 5¹²006¹²2c. Beeswax, 25⁰⁰27c.

Since our last report we have had a very good market for honey, and the demand has been very good for all grades, especially for sections of the best quality, and the demand is good now and small supply. We encourage shipments of best comb. Extracted, fair demand. A. V. BISHOP & Co.

TA RISE

To say to the readers of the BEE JOURNAL that

DOOLITTLE ...

has concluded to sell QUEENS in their season during 1899, at the following prices:

- 1 Fintested Queen \$1.00
- 6 Fintested Queens 4.50
- 12 Fintested Queens 8.00
- 1 Tested Queen 1.50
- 3 Tested Queens 3.50
- 1 Selected tested queen 2.00
- 3 " " Queens 4.00
- Subject Tested Queen, previous season's rearing, \$3; Extra Selected, for breeding, the very

best, \$5.00. About a pound of Bees in a 2-frame Nucleus, with any Queen, \$2.00 extra.

Circular free, giving full particulars regarding each class of Queens. Address,

G. M. DOOLITTLE,

CONVENTION PROCEEDINGS

Report of the Michigan State Convention.

BY W. Z. HUTCHINSON.

The Michigan State Bee-Keepers' Association met in annual convention Dec. 30 and 31, 1898, in Woodman's Hall, at Reed City. For several years this convention has not been a great success in point of numbers. When a man gets little or no honey, he has no money with which to attend conventions. This time the convention went into the heart of the willow-herb district, where the bee-keepers get honey, if any one does, and there was really quite a respectable crowd. Altho there was no set program, the proceedings were of interest and profitable. This plan was not adopted because any one thought that it possessed any special merit, but because the secretary was too busy to get up the program. If there is the right kind of a president in the chair, as there happened to be this time, this plan is all right. Another thing, it is now three months since the convention met, and the secretary is now writing up the proceedings. I think that the Michigan convention better choose some other man for secretary—one who can give more time to the work.

But to return: Slips of paper were past around, and the members asked to write questions and pass them up to the president, who read them and selected one for discussion. When one topic was thoroughly discussed, another was taken up.

THE MATING OF QUEENS.

T. F. Bingham—Other things being equal, is an Italian queen more likely to mate with an Italian drone than with a black drone?

J. M. Rankin—We have been trying at the Agricultural College to breed for length of tongue in the bees, and, of course, we wish the queens to mate with Italian drones, and we succeeded. I think that there is no difference as to the likelihood of a queen mating with a black drone or an Italian drone, that is, other things being equal.

Mr. Bingham—I have noticed that it is difficult to keep Italians pure. Three years ago my bees were all pure Italians, now they are mixed.

W. Z. Hutchinson—When I began bee-keeping I had black bees, and all of the bees in my neighborhood were black bees, with the exception of a few colonies of Italians that were a mile and a half from my place. It was a sort of a puzzle to me that one-half of my queens should mate with these distant drones, when there were so many black drones right in the yard. Later, I read the views of some of the leading bee-keepers that queens or drones, or both, had a disposition to fly far from home when mating. It

seemed a provision of Nature to prevent in-and-in breeding. When I began rearing queens for sale I found that I must get rid of all black drones in my neighborhood, but it was not until I had Italianized all of the bees within about three miles of my apiary that I finally succeeded in getting all of the young queens purely mated. With all of the bees Italians within three miles there were *none* of the queens mated, and there was no trouble in keeping my bees pure Italians. People say that Italians will "run out," and go back to the black blood, so to speak, but this isn't true. If an Italian apiary is surrounded by black bees nothing is more certain than that these Italians will eventually be superseded by hybrids. The same thing would occur if a man should start an apiary of blacks in a neighborhood filled with Italian bees. Mr. Aspinwall restrained the

A. C. Sanford (See page 250.)

queens in their disposition to roam by cutting from 1 to 1 1/2 inches from each wing, and the result was that almost all of them were mated by Italian drones, while black bees were in the vicinity.

Mr. Rankin—I think that a caution ought to be given in regard to this clipping. At the college we clipped 62 queens, and only three or four of them were mated. One of those

that mated was clipped only the 32nd of an inch, and one was clipped as much as $\frac{1}{4}$ the length of the wing.

PLAIN SECTIONS AND FENCE SEPARATORS.

L. C. Woodman—I have used 100 cases of plain sections. The season was poor, but I cannot say very much either for or against them. The fences are expensive, and the bees glue them up considerably.

Mr. Powers—I have used both styles of sections. The sections of the plain style are better filled. The separators are just as easily cleaned.

H. G. Gifford—When plain sections are used we get heavier combs and less pop-holes, and there is a saving in shipping-cases.

H. S. Collingwood—I want plain sections, but not fence separators. I want slats on the separators, so that I can use plain sections, but I do not want any fence separators. Here he showed a fence separator in which most of the cracks were filled with propolis.

Mr. Bingham called attention to the fact that most of the openings were too narrow.

Mr. Hilton called attention to the fact that the separator had been used at the outside of the super where the bees could not get behind it, and that and the narrowness of the openings accounted for the great quantities of propolis that had been used. He said that the A. I. Root Co. acknowledged that some of the first fences that they sent out had too narrow spaces. The fear of "washboardy" had led them to make the spaces as narrow as they had. This fault has been remedied.

Mr. Bingham—There is no question that the use of plain sections allows of a saving in shipping-cases, but there are other considerations. Here is one: With tight or closed separators the bees will begin upon only a few sections in the center of the super, and if the flow is slow, or if it is near the close of the harvest, they will keep on and finish up those few sections that they have begun working upon, when, with no separators, they are more inclined to spread out and begin work upon a large number of sections, and perhaps not finish any of them. With tight separators there will be less unfinished sections than with no separators, and it seems as if open separators might have a tendency in the way of encouraging the bees to spread out and begin work upon more sections than they can finish.

Mr. Hutchinson—I was over to the convention of the Ontario bee-keepers last December, and Mr. Jacob Alpaugh, who has had much experience in comb-honey production, took the same view as that advanced by Mr. Bingham, viz.: that separators have a tendency to keep the bees from spreading out and beginning more work than they will finish. That is, they seem to look upon each compartment between the separators as separate from the rest of the super, as independent in itself, and are more inclined to finish up work that is begun than to spread out and begin more work. In other words, tight separators seem to have a tendency to cause the bees to concentrate their efforts.

Mr. Bingham—Perhaps some of you may remember the Betsinger separator. It was made of coarse wire-cloth. The openings were large enough so that a bee could pass thru. If these openings had been too large I suppose that the bees would have made little warts upon the surface of the comb. The Roots have been very careful in this matter of plain sections and fence separators. They are working slowly as they did with the deep-cell foundation. They are not crowding these things. Fence separators may yet be thrown entirely out of the market.

Mr. Rankin—At the college we gave the plain sections and fence separators a trial. We filled one-half of a super with plain sections and fence separators, and the other half with old-style sections and old-style separators. The plain sections were better filled around the edges.

Mr. Bingham—When we see how easy it is for a firm like the Roots to make a mistake, we'd better be careful how we adopt anything about which there is even an opportunity for making a mistake.

NEEDED FOUL BROOD LEGISLATION.

The secretary read a paper from Mr. A. D. Wood, of Lansing, which went to show the difficulty of doing anything in the way of suppressing foul brood so long as there was no better law upon the subject. At the time the old law was past it was supposed that the only possible thing to do with a colony affected with foul brood was to burn it up. We have since learned that it is possible to save the bees, to disinfect and use the hive, to boil the honey and to melt the combs into wax, and to thus get rid of the disease with but little loss except the labor. The trouble is that

many bee-keepers have only a few colonies, and are not specially interested in bees. They do not know anything about foul brood, and do not recognize it when it first appears, and would not know how to treat it if they *did* recognize it. It is neglected, and colonies become weak in numbers, are robbed, and the seeds of the disease are thus spread from colony to colony, and from apiary to apiary. There is scarcely a county in the Lower Peninsula that is free from this disease; and until there is someone who has the authority and skill to step in and help bee-keepers to crush it out, it will continue to spread. Over in Ontario this disease threatened to wipe out the industry of bee-keeping when an inspector of apiaries was appointed. He has now been at work several years, and the disease is fast disappearing from the Province. Wisconsin has followed in the steps of Canada, and now has a similar law and a most efficient inspector. Illinois and New York are also working to get a similar law. Colorado has a foul brood law. There is too much machinery about the old law. There is too much trouble to get it enforced. If it turns out that there is no foul brood where it was suspected, then the man who complained is shouldered with the expense of the examination. This fear of being called upon to bear the cost deters many from complaining that would otherwise make a complaint.

Mr. Rankin—This disease is certainly on the increase. In Sanilac county I found an entire apiary dead from foul brood.

Pres. Hilton—We need protection from foul brood. The old law was all right at one time, but now it is different. Many of you probably have never seen foul brood, and do not know what it is like, and I hope you never will. The brood dies and turns a dark brown, and it is stringy andropy, and emits a disagreeable odor. Seeds of the disease get into the honey, and any of this honey carried to some other hive starts the disease there, and so it goes. Some of you may think that there is no foul brood near you, and that you will never need the law in your own personal case. This is something that you cannot be sure about. It may be nearer than you think. Even if it isn't the way to keep it away from you is to have it stamped out wherever it may be. If we as a body ask for this law, and show the legislature that it is really needed, it can be secured without a doubt.

Upon motion of Mr. Bingham, it was unanimously voted that Mr. Rankin be instructed to draft a bill similar to the Ontario or Wisconsin law, and secure its introduction to the Michigan legislature.

THE HEDDON HIVE AND MANAGEMENT.

D. R. Van Amburgh—With the Heddon hive I put on the sections when the bees are ready regardless of whether the hive is composed of one or two cases. It is from the swarm that I get the honey. I give the supers to the swarm.

Mr. Hutchinson—My practice is the same as that of Mr. Van Amburgh. As soon as the bees are nicely at work in the first super, and it is half or two-thirds full of honey, that is, the sections have reached that stage of completion, I raise up the super and put another underneath. I fill all sections full of foundation. When the bees have made a good start in the second super, and honey is coming in at a good rate, I raise both supers and put another underneath. It must be remembered that the force of bees in the hive is rapidly increasing at this time of the year, and it does not take long for enough to hatch out to fill a super. By the time that it is advisable to add another super, if that time comes, it is likely that the top super will be ready to come off. If the bees are a little slow in completing the corner sections I would not leave the super on for them to be completed, but take it off and take out the unfinished sections in the corners. As soon as enough of these unfinished sections have accumulated to fill a super I fill one and put it upon some colony. I would not tier up supers more than three high. If a colony is crowded for room, and has three supers, and the top one is not ready to come off, I would give it, bees and all, to some weaker colony. I have never had quarreling when I did this. In hiving a swarm, I hive it in two cases of the Heddon hive, with only starters in the frames. It is hived upon the old stand, and the old hive set by its side. The supers are transferred from the old hive to the swarm. In about three days, after the bees have quieted down and recovered from their swarming-fever, I remove the lower case. If hived in only one case there is danger of their absconding, but there is no danger after three days. On the seventh day the old hive is moved to a new location. This robs it of its surplus bees at the time when the young queens are hatching, and, as a rule, there is no after-swarm. If there is an after-swarm I usually go thru the hive and cut out the remaining queen-cells, and

hive it back again, when the trouble is over. Like Mr. Van Amburgh, I get my surplus from the swarm. This contraction of the brood-nest leaves a colony in a condition that is not strictly first-class for wintering. If there is a fall flow, an additional case can be given, and the bees will build up into a good colony. If the location is such that there is no fall flow, then I unite the swarms at the end of the main honey harvest. To do this I remove one-half the queens about two days before I wish to make the unions. The queenless colonies are carried and set up on the top of those having queens. Queenless bees are much more inclined to give up their location than is the case with those having a queen. There is also less danger of quarreling if the bees of one colony are queenless. This, in brief, is a sort of outline of my management with the Heddon hive.

Mr. Bingham—I would like to know how small a colony will winter well. I may say, however, that I think that colonies are more nearly of an average size in the fall than many of us imagine.

Mr. Hutchinson—I prefer a colony of ordinary strength, but the bees must be young bees. A large colony of old bees is not of much value compared with even a small one of young bees.

THE BUILDING OF A HONEY-HOUSE.

The question was asked, "What kind of a honey-house should be built for 100 colonies of bees?"

Mr. Hutchinson—My honey-house was for 100 colonies. It was only 8x10 feet in size. The sills were 2x4 inch oak scantling laid upon stones. The sides were of boards nailed to the sills and plates. It was battened. The boards were painted a dark red, and the battens white. It had a peaked roof, and there was a door in each end and, a window in each door and in each side. These windows allowed us to see if swarms were coming out. The windows slid to one side, and there was wirecloth over the windows on the outside. This wirecloth extended up above the windows, and was held out a little distance from the side of the building so that bees could crawl up and escape. This building answered very well as a honey-house, but we had another larger building near by that was used for a shop and store-house. Our honey-house stood in the middle of the apiary.

H. S. Wheeler—I would like a larger house than that. I want one in which there is room to do some work, also to store from 4,000 to 6,000 pounds of honey. I would have the house at least as large as 15x16 feet.

Pres. Hilton—I agree with Mr. Wheeler. It costs but little more to build a large house than it does to build a small one. I would have it at least 12x16 feet.

Mr. Bingham—I would have a trap-door in the roof so arranged that it can be opened, and the opening closed with wirecloth. When extracting in hot weather the heat in the closed building is something that is almost overpowering. This door in the roof would allow the heat to pass off. I would have wirecloth over the windows, but inside the glass instead of outside of it. I would have my work-shop in a separate room from the honey-room. We often wish the honey-room closed, and it is not a comfortable place in which to work.

ADVISABILITY OF HAVING OUT-APIARIES.

The question was asked as to how an out-apiary should be managed in swarming-time.

Mr. Woodman—If I had it to do I should want a cheap hand to help me.

Mr. Bingham—I would keep a close watch at each apiary and see where the bees did the best, and take all of the bees to that place. I doubt if it pays, many times, to have out-apiaries. It increases the work wonderfully.

THE POSSIBILITIES OF THE WILLOW-HERB.

Mr. Wheeler told how quickly a colony had filled the combs of an upper story when willow-herb was in bloom.

Mr. Gifford—I once hived a swarm, and in seven days it swarmed again. I examined the hive and found the 10 combs full of honey, except a few patches of brood, and the two supers of sections were also full.

Mr. Bingham—I object to the publication of such stories. It induces men to go into the business only to be disappointed. In this instance they are probably true, but they are not representative yields. Michigan does not yield more than 15 pounds per colony on the average.

Pres. Hilton—For eight years I kept a careful account, and my average yield for the eight years was 75 pounds per colony.

Mr. Bingham—Yes, but that was when the woods were full of honey. It was when Mr. Root got the cistern full.

Pres. Hilton—I presume that Mr. Bingham is really

correct in saying that the average yield for the whole State of Michigan is not more than 15 pounds per colony, but in this region 50 pounds per colony is a fair average, and I can afford to hire a man to care for my bees and pay him good wages, and make money out of the business. It must be remembered that bees cannot be neglected if we are to get good yields.

Mr. Van Amburgh—I have taken as much as 50 pounds a colony in a little basswood flow; but I have had basswood harvests in which I got only five pounds.

LAYING WORKERS, HOW TO DETECT THEIR PRESENCE, AND HOW TO GET RID OF THEM.

In reply to a question as to how the presence of a laying worker could be detected, Mr. Hutchinson said:

"It can be detected by a large number of eggs being deposited in one cell. The eggs are seldom in the bottom of the cell. Perhaps the worker cannot reach to the bottom of the cell. They are always on one side, and near the bottom. When the eggs hatch all of the larvae soon die except one, and when the cells are capped over they have a conical or raised capping the same as the capping over drone-brood. It is very seldom that a laying worker is seen. Once or twice I have seen a worker laying eggs, or at least it *lookt* as if she was laying. I caught and killed her, but it did not stop the laying of workers. I presume that there is more than one in a colony."

Mr. Bingham—The bees act uneasy. Thump on the hive, and they will keep up a humming for a long time. Thump on a hive containing a colony with a queen, and the bees will make a short hum, or buzz, and then stop.

Mr. Hutchinson—The quickest and easiest way of getting rid of a laying worker is to unite the colony with some other colony having a laying queen. Or the colony with a laying worker may be moved away and a nucleus with a queen set in its place. The workers will return to their old home and join the nucleus. When most of the bees have joined the nucleus the rest of them may be shaken down in front of the nucleus, and all will be well.

PREVENTION OF BUR-COMBS.

Mr. Rankin—We have tried various frames, and the Hoffman frame with top-bars 1 1/8 wide and 7/8 deep, spaced 1/4 inch apart, gives us the least bur-combs.

Pres. Hilton—My experience is the same. With this frame I see no need of a honey-board. Such a top-bar also has a tendency to keep the queen out of the supers.

PLACE OF MEETING AND ELECTION OF OFFICERS.

Thompsonville was selected as the next place of meeting, and the following officers chosen: President, Geo. E. Hilton; vice-president, H. Gifford; secretary, W. Z. Hutchinson; and treasurer, J. M. Rankin.

W. Z. HUTCHINSON, Sec.

Purity of Drones from a Mismatched Mother.

BY G. M. DOOLITTLE.

THE following was referred to me to answer in the American Bee Journal. I don't know why, for I do not profess to be informed on such matters, as do some of our more scientific brethren in apiculture. But I will try to throw what light I can on the subject from a practical standpoint. Here is the subject referred to:

EDITOR YORK:—The Scientific American supplement No. 127 contains an article on the honey-bee, reprinted from a pamphlet issued by the United States Department of Agriculture as Bulletin No. 1, Division of Entomology. The article closes thus:

"The fact that drones develop from unfertilized eggs is to be noted as having an important practical bearing in connection with the introduction of new strains of a given race or of new races of bees into an apiary. From a single choice home-bred or imported mother, young queens of undoubted purity of blood may be reared for all of the colonies of the apiary, and since the mating of these young queens does not effect their drone progeny, thereafter only drones of the desired strain or race and pure in blood will be produced, rendering, therefore, the pure mating of future rearings fairly certain if other bees are not numerous within a mile or two. Eventually, also, all of the colonies will be changed to the new race, and without admixture of impure blood, provided always that

the young queens be reared from mothers of pure blood mated to drones of equal purity."

Now, I wish you would answer this thru the Bee Journal, or have a specialist in queen-rearing answer it, namely: Does experience teach that queens from a mother of undoubted purity of blood produce ONLY drones of the same purity as the old queen, no matter to what race the drone belonged which the young queen met on her wedding flight? That is, does a pure Italian queen, mated to a Carniolian drone, produce hybrid workers, but PURELY Italian drones?

I have often heard that the color of the drones of any colony would show the purity or impurity of blood more certain than the color of the workers, which is contradictory to the above.

AUGUST F. KOCH, PH.D.

In the first place I object to the term "purity" as often applied to the Italian bee, and as spoken of by the writer of the above. Nearly 30 years of experience with the Italian bee has thoroly convinced me that it is not a *pure race* of bees, but only what would be called "thorobred." If such is the case, which I shall soon try to prove, then all talk about keeping an apiary of such bees pure is only a case of reasoning upon a false base or beginning, to start from. When it comes to breeding the Italian bee "to the feather," as it is termed by poultry-men, such bees are "not in it," and never have been, for the queens vary all the way from being as dark as a pure-blood German queen to one whose abdomen is of a rich orange color the whole length, even to its extreme tip, on the best specimens; while the drones and workers vary nearly as much, altho no worker-bee has ever been reared whose extreme tip was of an orange color.

Now if the queens coming from Italy, or "imported stock" as they are usually termed, produce workers with only three dark or leather-colored bands upon their abdomen, and drones which the ordinary observer would pronounce only as black drones, while their young queens vary all the way from black to those being ring-streakt, speckled and spotted, the same as being called *pure* Italians, how comes it about that any careful breeder can take these bees and by selection soon come into possession of bees so yellow that there is no sign of black on the queen, very little on the drones, and only a very little of dark or black on the extreme tip of the workers? Is it not self-evident to any unprejudiced mind, that there can be no establisht purity in the *imported* mother from which we started?

Take a black or German queen in her purity and try the same line of breeding for a whole century, with none but drones from a German queen, and you will have only common black or German queens, workers and drones at the end of the 100 years. So if we are to start from the purity side for any experiment as to whether the drones are affected by the young queen meeting the drone of a different "blood," we must start with the German queen, or something we know came from a *pure* race of bees.

Then there is another point I wish to call attention to, which is, where the statement is made that success can be attained along this line of pure mating of queens, "if other bees are not numerous within a mile or two." Herein lies one of the weak points in "breeding for purity," which is very fallacious, and, strange to say, this fallacious part is more often put before the public than the real truth.

All careful observers know that a distance of at least five miles must intervene between the race of bees we would desire to keep pure and that of any *single* colony of another race, else all our breeding for purity is of no avail. Yea, and were I to say just what I thought I should say that the distance should be at least *seven* miles, from the experience I have had since I came into possession of my out-apiary. When I bought this out-apiary it was composed of nearly all black bees, tho some of the queens had evidently mated with drones from dark Italian stock, that being the kind of Italians chiefly kept where other but black bees were used, up to this time. At about the time I came into possession of this out-apiary, I became interested in what is termed the "five-banded" or golden Italians, those bred in this country from the dark imported stock, as before mentioned, till they were as yellow as gold.

Having become interested in these yellow bees I kept down drones from the dark Italians and allowed much drone-comb, consequently many drones of the yellow variety to come forth, and the result is, that, altho this out-apiary is fully five miles distant from my home yard, fully one queen out of six at the out-apiary shows by her progeny that she mated one of the yellow drones.

No, no, friends, there is no such thing as pure mating of queens where apiaries of different races are located "within a mile or two" of each other, and he who thus breeds, expecting to reap any certain results, is destined to an uncertainty of affairs which is not pleasant to contemplate.

All familiar with the flight of drones know that they have places where they congregate by the thousands, if not

millions, coming to these places from all over a region from five to seven miles around, and when the queen comes to these congregating places she is as apt to meet a drone from a "scurf" breed as she is one of those choice, nice, yellow "gentlemen" you would have her secure as her partner.

Late in the fall, or in early spring, drones nor queens fly so far, consequently we are more sure of pure [?] mating with Italian bees than at other times of the working season. For this reason I select combs of drone-brood from my choicest colonies, near the close of the honey season, and mass this drone-brood in a colony kept queenless and fed bountifully, so that these drones are kept after other drones are killed off in the fall, when they are "hand-pickt," so that only the best remain when young queens are reared, and a satisfactory result obtained.

And now to the real question which it is desired should be answered. There can be no question but what the *drone is the son of his mother*, for all queens can lay eggs which will perfect drones, even tho they never meet a drone, or become capable of laying worker-eggs. From this standpoint it is easy to say, that "as is the mother so will the son be," and this is what the scientists have claimed thru all the past. But there are those who claim that the *son* of the mother of a pure black queen, mated to a yellow drone, is not the same son, to all intents and purposes, that he would have been had this queen never met a drone at all, or had she met a drone of her own race; and I believe this last to be correct, when we come down to the very fine points of "breeding to a spot or feather."

I am fully persuaded that a succession of breeding along this line will result in a mongrel race, thru the contamination of the queen in mating; but the process will be so slow that, when practically applied, the writer from the agricultural department of the United States is very nearly or quite right. I presume the writer of the reference given was none other than Frank Benton, a man whose opinion, along these lines, is fully equal in value to that of any other in the world.

Rheumatism Cured by Bee-Stings.

BY ELD. DANIEL WHITMER.

IN the forepart of June, 1898, I called on Editor York, and in our conversation I remarkt that I had not reported my work with the bees for a number of years, tho having manipulated them for about 20 years, and having been a constant reader of the American Bee Journal for that time. He replied that I ought to let my light shine. Therefore, remembering the best of all books giving the intelligence that if the light that is in thee be darkness, how great is that darkness, here goes.

First, then, I call the attention of the bee-keeping fraternity to the dreaded and unenjoyable rheumatism which afflicts and affects so many persons who so much desire a remedy giving relief and effecting a radical cure to the sufferer. I believe that bee-poison, with some people, is a good remedy; it has proved itself a bonanza and antidote to the writer for many years.

Prior to my entering the bee-industry, I had been a victim of the disease in its different forms, attacking the limbs and other portions of the body. Finally, by overwork in manual labor, I was attackt with sciatic rheumatism, resulting in paralysis of the back, thighs, kidneys, bladder, etc., and was under the doctor's care and confined to my bed and room for three months.

Under the doctor's treatment I became convalescent, but unable to perform manual labor on the farm. As yet the great numbness in my limbs was so present that in my invalid condition I chose apiculture as a pursuit to give me a livelihood.

One day in handling a colony of bees I became somewhat careless in the manipulation, and irritated the bees to the extent that they rusht out of the hive and stung me desperately on the most numb parts. If I had no feeling before, it was evident I had then, for I just danced as I never did before, for I don't believe in it.

In 24 hours I was a well man, so far as rheumatism was concerned, numbness all gone. I am liable to get it in the fall and winter. It has returned three times in 20 years, and subsided every time when I got out with my bees in the spring.

I reported my cure to my physician, giving the remedy that did it. He stood before me staring and with amazement, and said that the poison of the bee-sting would have that effect. So at the next medical institute, at Chicago, he

reported my case and cure to the medical faculty, after which I had calls for bees that the poison could or might be extracted in alcohol to be given internally as a remedy for rheumatism.

My general health has improved during all these years.

Feeding Sugar Syrup to Fill the Brood-Combs Prior to the Main Honey Harvest.

BY W. W. M'NEAL.

I CANNOT but think it a mistake on the part of anyone who resorts to the use of sugar syrup in the manner spoken of to secure a crop of honey. The feeding of it to stimulate the queen to increase activity, thereby getting the combs filled with brood instead of syrup is certainly a more practical method and less questionable. Feeding bees is a fussy, unpleasant work at best; when the word is spoken and the act performed, the story will reverberate up and down the valley and adjacent hills till they who eat honey decide to buy it of some one else. If the colony is allowed an abundance of good, ripe honey the fall previous, or given a sufficiency at one feeding in the spring of the year, they will usually be found able to take care of their share of the honey crop when it comes.

To feed bees sugar syrup and get it stored in the brood-combs in the manner they store when gathering from the flowers, is something every one cannot do, or will not take the time to do. If only a little is fed for a goodly number of days, surely none of it can be stored for future use unless the bees are gathering from other sources enough to meet their needs, and if they are given syrup in quantities to enable them to do this, it will most certainly be done at the expense of brood or numerical strength.

When the honey harvest arrives the result most likely will be one of two things; The queen, if she be one or two years old, will issue with a swarm; if she be of the current season's rearing, the bees will clear the brood-combs for her of the syrup, and carry it into the supers. If they never do this, why is it that a swarm having a young fertile queen and hived on drawn combs during a good honey-flow continues to work right along in the sections for sometime after the flow has ceased? Will those who insist that bees do not carry above a portion of the syrup when the brood-combs are crowded at the opening of the harvest consent to feed a dark grade of extracted honey prior to the coming of the *white* honey? The addition of sugar syrup to well-ripened clover or basswood honey does not improve the quality or color, be it done by the bees or the apiarist. The darker grades and thin, watery, unripe honey may be made better; but to sell it under the name of *honey*—well, say, my esteemed bee-keeping friend, wouldn't you feel just a little bit wronged if some one to whom you had paid the price of best pure honey would deliver instead an article composed of sugar syrup and honey, and the whole labeled "honey?"

Bee-keepers should not be too loud in their condemnation of glucose when their own houses of stone are composed so largely of glass. I feel that no one can be more bitterly opposed to the use of glucose with honey than myself. Such adulteration cannot be other than a voluntary effort to deceive for the sake of gain. But to ignore such wholesome proof as the bees produce, that the syrup or honey of the brood-combs is oftentimes carried into the supers—a portion of it, I mean—and there stored in the comb along with the honey being gathered from the field, is a moral slackness which gentlemen of the brotherhood should be very careful of.

O haste the time when there will be made known some simple, reliable means of detecting the presence of glucose or cane sugar in honey! Then our patrons may read from the label on can or bucket the surety of the genuineness of its contents.

I am prone to believe, owing to the largely varying flavor of pure honeys, that adulteration is not nearly so prevalent as the belief thereof. But a world of suspicion on the one hand, and a company on the other practicing the adulteration of honey, and no ready means to convince a quizzical customer that the honey one is selling is, beyond peradventure, strictly pure, has changed the selling of honey in many places from a pleasant to an unpleasant one.

When honey is bought in a distant market to hold one's trade, great care and judgment should be exercised in selecting and in the handling, if the apiary be close to where the honey is kept. Honey that differs widely in flavor from

what people are accustomed to buy will generally find poor sale; but it may be a fruitful source of foul brood contagion, and so prove to be a pretty expensive way of holding the trade in honey. Alfalfa extracted honey is certainly pleasing enough in body and flavor to suit the most exacting purchaser; but even this I would not feed to my own bees without first diluting with water and boiling thoroly.

With proper precaution I believe it to be to one's interest to buy when his own crop is short. As well as I like the taste of alfalfa honey the daintiest little mouthful distresses me as if it were poison pure and simple to my stomach. I have eaten of a good many kinds of honey, but none save the alfalfa ever hurt me. I have sold it quite largely with the best of satisfaction to all parties concerned, and know of but one other case who, like myself, was made sick from eating it.

A good article of extracted honey, to my notion, is better than the same in the comb, and I fully believe that honey in this form will be the only way it can be produced at a profit in the near future.

The sooner bee-keepers cease to stir up further opposition by the injudicious feeding of sugar syrup the better it will be for the pursuit.
Scioto Co., Ohio.

Law and Honey Prices—A Reply to Mr. Doolittle.

BY EMERSON TAYLOR ABBOTT.

THERE is a certain animal which is said to become very much excited at the appearance of a red rag, and some of my remarks seem to have had a like effect on Mr. Doolittle (see page 195), yet, for the life of me, I cannot tell why. There seems to be no reason why he should lash himself into such righteous indignation, unless he has looked at the dark side of things so long that his vision of the crown and glory of life, health and happiness, has become a little blurred.

Mr. Doolittle, this is not a radically bad world, and "God is not dead," even tho they did feed our soldiers on bad meat, and just now we are engaged in an inglorious effort to kill off a lot of half-civilized Filipinos. It is true, however, that some men are a good deal richer than an exercise of common honesty would seem to warrant, but I see no advantage in becoming greatly excited about it.

I have very positive views on the subject which Mr. Doolittle touches, but I am thoroly confident that the American Bee Journal is not the place to discuss them. I think I can see these things just as "clearly" as Mr. D., but perhaps they may not look the same to me as they do to him. Let that be as it may, I want to set myself right, for I am convinced that the two articles referred to, taken as a whole, do not teach what Mr. D. tries to write into them. Perhaps I did not express myself clearly, but what I wanted to say, in the pure food talk, was that no law should be past *with a view to raising or lowering the price of any product.* Especially should no law be past *because it will enable a certain class of people to get more for their products.* This is not what law is for, but to promote the *common good.* Briefly, to illustrate, I do not believe we have any right to pass a law against the adulteration of honey *because it will raise the price of honey,* but because it is a *fraud to adulterate,* and all frauds should be suppress.

Bless your soul, Mr. Doolittle, I had no idea of discussing what effect laws *do* have on the price of things when I said, "Law has nothing to do with increasing the price of the produce of any individual;" and I still insist that this is not the province of law, but rather to guarantee unto every man "Life, liberty, and the pursuit of happiness." Perhaps it would have been better if I had said, "Law should have," etc.

I want to enter a mild protest against Mr. D.'s repeated assertions that evidently Mr. Abbott believes so and so, for I am quite sure he does not know what I do believe on these subjects. I have never discuss them in any bee-paper, nor do I intend to do so. There is not much occasion just now to discuss low prices of anything in this locality, especially the price of comb honey, for there is very little to be had, and I could sell a great deal of it at remunerative prices, if I only knew where to get it. Wonder which it was, *law or politics* that brought about this state of things!

Let me say, in conclusion, that I honestly believe that the adulteration fraud is the gigantic crime of the century, and a disposition to wink at it shows a lack of moral sentiment which should startle into activity the most sluggish and indifferent citizen of a free country. Adulteration ignores the foundation principles of all moral sentiment, and undermines two of the recognized basic ideas of legiti-

mate trade and commerce, namely, that a contract is the agreement of two minds as touching one thing; and that every man who has come into the lawful possession of any article has a right to fix the price at which he will part with it. If he makes the price so many pounds of honey, and you give him half the amount in glucose, you defraud him just that much, and every man who does it is a criminal, and, as such, should be punished severely. If this raises the price of honey, all right; if it lowers it, all right; but let us be honest, "tho' the heavens fall." No, Mr. Doolittle, your "pet hobby" is not of more importance than this. Nothing can be.

Buchanan Co., Mo.

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Farm-Stock Damage an Apiary.

I have 156 colonies of bees. We have a man here that is against bee-keeping; he believes in spraying when in blossom. There was a law past last winter that stops him on that, but he pastures 50 head of stock on the byways, which have been in my apiary and damaged the bees to a great extent, turning two hives over, pushing several from the stands. The disturbance is bad, the bees fill up with honey in cold weather, and can't fly.

NEW YORK.

ANSWER.—I don't suppose there's anything different about the case from a case of damage in which there were no bees in the case. The probability is that your laws are such that one is not allowed to let his stock run in the road, and is responsible for damage done by them if they are allowed to run at large. In that case you would sue before the proper officer, probably a justice of the peace, the same as in any damage suit. If there is any special difficulty in the case, you can count on help from the United States Bee-Keepers' Association, providing you were a member before getting into trouble. If you are at present a member you are one of the wise ones, for some put off securing membership until they get into trouble, and then it's too late. Besides that, every bee-keeper should be willing to pay his dollar a year to help put down adulteration. A dollar spent in that way may put several dollars in his pocket in increase of price of honey.

Grapevines for Shading Hives—Frames of Granulated Honey.

1. Are grapes good for bees?
2. I am thinking of putting a grapevine at every other hive for a shade, and also for the fruit. What is your opinion of it?
3. Would the grapes make a good shade?
4. I have about 150 or 200 brood-frames with granulated honey in them. Is there any way to get them out, besides tearing up the combs? They were taken off last fall.

KENTUCKY.

ANSWERS.—1. At different times my bees have worked on grapes after birds have picked holes in the grapes, and I don't know that any harm came from it.

2 and 3.—So far as fruit is concerned, grapes will do very well planted in an apiary. For shade a grapevine is not so very satisfactory, unless you have a trellis overhead, which is expensive.

4. Don't think of destroying the combs. Spray them with water and put in the hives for the bees to clean up, spraying again as often as needed.

Bees That Have Foul Brood.

In preparing my bees for winter last season I found, to my great surprise, that 2 colonies of the 12 were entirely destroyed by foul brood, and that every other one showed traces of the same disease. I would have found it out before, but the only time I have to work with them is on Saturday afternoon of every month, as all the remainder of my time is taken up with work and study.

Is it possible to cure the remainder, and how? is what I would like to know. I should like to know what books or pamphlets contain the most information on that subject, as I would like to make a thoro study of it, and might bring some of my knowledge to assist in getting an easy cure for it.

As assistant engineer of a large ice-machine manufacturing establishment, I thought that maybe a little chilly air supplied to them might affect a cure, as we have an abundance of it at our disposal from 0 to 40 degrees, Fahr., below.

For the past few years I have derived much pleasure in handling my bees, and only regret that I haven't more time to give them, but I should feel very sorry to be obliged to destroy them

all, as I have purchased all the queens from different apiaries, and find pleasure in trying to keep some from swarming, making some work, and supplying upper stories to others that seem to turn out to honey, they gather it so fast. Of all the queens I ever had I got one from the South that beats anything I ever saw swarming, and the swarms manage to get in the highest branches of the trees, and afford the entire neighborhood amusement watching us get them down and hiving them.

All my hives are of Root's latest and in summer are entirely covered by caladians and cannas, which makes it difficult to handle them, but they set off the apiary beautifully, which is nothing more than a large flower-garden.

OHIO.

ANSWER.—Send 25 cents to the publishers of this paper and get Dr. Howard's pamphlet on foul brood, and you will have the best thing in the language.

I've never yet heard of foul brood spores being injured by cold. It's the extreme of temperature at the other end that's hard on them. But I'm not sure whether a continued application of 40 degrees below zero has ever been faithfully tried.

Letting Bees Fly After Shipping.

When a colony of bees has been shipped a distance, and confined for several days, is it best to open the hive and allow them a flight upon arrival? Or, let them get quieted down first, and open the hive say in the evening?

IOWA.

ANSWER.—I don't know of any reason why it is not better to let them out as soon as possible.

Wood Foundation-Splints Instead of Wiring.

1. Why will not wiring brood-frames do just as well as to muss with the sticks you use?
2. Would not the Van Deusen wired foundation be just the thing if it is put in the new grooved top-bar, and let the wires run up and down in the frame?
3. Had you tried wire in any form before you finally decided on the sticks?
4. Are there any other advantages over the wires, by using sticks, than the prevention of sagging or stretching?
5. It seems to me your sticks don't prevent the comb from breaking loose from the top-bar in moving bees.

S. DAKOTA.

ANSWERS.—1. It is no more trouble to muss with the sticks than to muss with the wire, and I have never been able to get as good combs with wire as with sticks.

2. Good combs might be secured thereby.

3. I have had wired frames in use by the thousand for many years—began using them from the first that wiring was made known; have perhaps 2,500 such frames now; have tried wiring horizontally, vertically, diagonally, and mixt, in fact in perhaps all ways recommended and some not recommended. Yes, I've tried wiring.

4. I have never been able with wires to have perfect combs built completely to the bottom-bar, and I have such combs with the sticks.

5. When a comb fills a frame completely from top to bottom, did you ever hear of its breaking away from the top-bar in moving? Probably the most popular form of wiring now is the horizontal. Do you think a horizontal wire that is half an inch or more below the top-bar will do more to prevent breaking from the top-bar than five sticks that are $\frac{1}{8}$ -inch or less from the top-bar?

Please remember that I don't insist that any one else shall use foundation-splints. I only say that so far as I have tried them I like them very much, and have just ordered 4,000 more.

Brood-Frames and Their Spacing.

There has appeared in the American Bee Journal a description of the brood-frames used in your hives. I have had several years' experience with different styles of frames, and have decided that your idea of a brood-frame is about right. Kindly give the dimensions of your frames, and who manufactures them.

What size nails do you use in spacing (brad or flat head), and how far from the end of the top-bar, and how far down on the side piece, are they driven?

CITY.

ANSWER.—Top bar, $18\frac{1}{2} \times 1\frac{1}{8} \times 7\frac{1}{8}$. At each end is cut out $7\frac{1}{2} \times 9-16$, leaving the end $5-16$ thick. A saw-kerf to receive foundation runs lengthwise along the underside of top-bar, $5-32$ wide and $\frac{1}{4}$ inch deep. End-bar, $8-9-16 \times 1\frac{1}{8} \times 3\frac{1}{4}$. The bottom-bar is in two parts, each $17\frac{1}{2} \times 1\frac{1}{2} \times 1\frac{1}{4}$. Only one of these pieces is nailed on when the frame is made, the other being nailed on after foundation is in place. The sheet of foundation is $16\frac{1}{2} \times 8\frac{1}{2}$. No wiring is used, the foundation being supported by five vertical basswood splints, $7\frac{1}{2} \times 1-16 \times 1-16$. These splints are boiled in beeswax and prest into the foundation while warm.

For spacers to hold the frames at the proper distance from each other, common wire nails are used $1\frac{1}{4}$ inches long with flat heads $3-16$ inches across. A gauge is used in driving in these nails so that the head shall project $\frac{1}{4}$ -inch above the surface. Two nails are on one side at one end, and two nails on the other side at the other end. The nail in the top-bar is about $1\frac{1}{4}$ inches from the extreme end, and $7-16$ from the top. The other nail is driven in the

end-bar about 2 $\frac{1}{2}$ inches from the bottom. Hold the frame up before you as it hangs in the hive, and on the side next you the two nails will be at the left, while at the right they will be on the side opposite. To hold the frame in proper place endwise, small staples are used about the same as window-blind staples. The staple is driven into the end-bar close under the top-bar.

It is only right to say that I'm not sure whether the width of these top-bars, 1 $\frac{1}{8}$ inches, with a space of $\frac{1}{4}$ -inch between them, is the very best. The bees build more brace-combs between the top-bars than are desirable.

Some of my frames were made by the A. I. Root Co., and some by the G. B. Lewis Co. I think neither of them make such frames, only to order.

Moldy Combs—Putting on Supers.

My Italian bees in 8-frame dovetailed hives have wintered well considering the cold weather we had here, being 20 degrees below zero, and one spell was 30 degrees. If I had not had my bees packed in winter-cases I would not have had a bee now. But the combs which contain the honey toward the back part of the hive are moldy and very damp. I saw water dropping off of them and lying on the bottom-board, and water standing in the empty cells at the bottom of the comb. They have lots of honey yet. What is the cause of the above conditions of mold and the combs sweating so? And is there anything I should do, or shall I let them go? Will they come out all right themselves?

The combs at the entrance of the hives are dry, and not moldy. The bees seem to be flying finely, and are very vigorous, trying their best to rob a colony of black bees.

2 They have four brood-frames about full of honey, and the other four about half full. Should I put on a super by the middle of April?
WEST VIRGINIA.

ANSWERS.—1. Probably the entrances were hardly open enough for sufficient ventilation. The parts farthest from the entrance would suffer most, the moisture settling there. The bees will probably correct the trouble of their own accord.

2. It is hardly wise to put on supers till a harvest comes from which they can store, but if you find the queen is crowded for want of room in which to lay, take out a full comb of honey and replace with an empty comb.

Taking Care of Combs of Honey.

I have six hives that the bees froze in. I cleaned the bees out, but the hives are full of honey. I want to keep them, as I have made arrangements with a neighbor for swarms to put into them. What will be the best way to do, to keep the moths out till used? Bees did very poorly here; 90 percent of those not stored are dead.
IOWA.

ANSWER.—A cool, dry cellar is a pretty good place, as in such a place the worms will make very slow headway. If such a place is not at hand, they may be kept above ground, being spaced well apart, where moths and bees cannot reach them. Look at them from time to time, and pick out with a wire-nail any worms that get a start. They may be brimstoned, but it takes very heavy brimstoning to affect worms in brood combs. Probably the very best way is to put a hive full of combs under a hive containing a strong colony.

The Bee-Keepers' Association—Enameled Cloth.

1. Where can I obtain the proper information in regard to joining the Bee-Keepers' Association?
2. Is it necessary to scrape the caps clean, providing they were used the year before?
3. Do you advise the use of enameled cloth over the brood-frames?
NEW YORK.

ANSWERS.—1. Right here. You probably mean the United States Bee-Keepers' Association. Send a dollar to the General Manager, Hon. Eugene Secor, Forest City, Iowa, and tell him you want to join the Association. Or, send to the Secretary, Dr. A. B. Mason, 3512 Monroe Street, Toledo, Ohio, or to the editor of this paper. You can hardly do a wiser thing than to become a member at once.

2. If you mean hive-covers, I should say it was not necessary.
3. That depends somewhat on how the hives are made. If the covers come within $\frac{1}{4}$ -inch of the top-bars, nothing of the kind is needed. If the covers don't fit down so close, then something in the line of sheets or quilts is needed. Perhaps, however, heavy sheeting is better than enameled cloth.

A Quintet of Questions.

1. I use shallow Hoffman frames (5 $\frac{3}{8}$ deep) for extracting. Would you advise me to get a Cowan extractor with baskets large enough to hold two of these frames in each basket? How would the No. 17 two-frame Cowan do?
2. Is it necessary or advisable to use a dummy or follower in the extracting-super when using Hoffman frames, as above described?
3. In hiving a swarm, which is the better plan (a) to have all the frames filled with foundation. (b) partly foundation and part

drawn-out combs. (c) or partly foundation and part $\frac{1}{2}$ or 1 inch starters alternately placed in the hive? Authorities seem to differ on these points.

4. Which is the best foundation to use in shallow frames, medium brood, light brood, or thin super? Should I use full sheets or starters? Will it be necessary or advisable to wire shallow frames 5 $\frac{3}{8}$ deep?

5. I can get good, strong colonies of Italian bees at \$7.00 or \$8.00 each; 1st swarms, at \$3.00 each; 2nd swarms, at \$1.50 each. Which would be the cheapest to buy considering the fact that increase of colonies is most desired? The full colonies would be in their own hives. For the swarms I would have to provide hives, frames, etc., buying bees only.
IOWA.

ANSWERS.—1. I don't know, and I'd be obliged if some one who has had experience with such shallow frames would answer. I should think the No. 17 you mention would work all right if it doesn't take too careful work to get the two combs in the same basket.

2. It is advisable to use a dummy with any kind of a self-spacing frame. Otherwise you can't easily get out the first frame.

3. You are right in saying authorities differ, so you can't expect me to do more than to give my own preference, which would be, first, full combs; second, full sheets of foundation. If I had to use part starters, I'd use them by themselves, and not alternately.

4. Light brood with one horizontal wire will probably work all right.

5. That's a hard one. If you'll tell how much the old colonies will swarm, it will be easier to answer; also what time you can get the first and second swarms. If they come early enough, I'd risk the second swarms. Take an average season, and perhaps the first swarms will be best.

Sections with Starters Left Over.

I have been watching the Bee Journal for some time to see if I could use my pound sections that were in the supers last year with the starters in, or whether I have to throw them all away. I have about 1,700 of them that are not drawn at all, but are just as when about in the sections last year.
NEW YORK.

ANSWER.—By all means use all the sections you have left over that are nice and clean.

"Adel" Bees—Zinc for Solar Extractor.

1. On page 150, New Jersey asks, "What are yellow-banded Adel bees?" You say you never saw any of them? Aren't you mistaken? Frank Benton says, "Select queens of any well-established race or variety may properly be called Adel queens." See Vol. XXXIV, No. 25, American Bee Journal, page 783.

2. Would a sheet of zinc be suitable for making a solar wax-extractor?
WISCONSIN.

ANSWERS.—1. The word "adel" is a German word meaning "nobility." Mr. Benton is right in saying that such a word might have been applied in a general sense to any strain of bees of good quality, just as any good strain of bees might be called "honey-getters." But if you should develop a particular strain of bees and call them "honey-getters," bee-keepers would be likely to respect that title as belonging to your strain of bees, especially if you used the name in some foreign language. So when Mr. Alley uses that name for a particular strain, I see no reason why his title to that name should not be respected. Instead of being a strain of Italians, Mr. Alley says they are from Carniolans. In a late letter he says: "Don't you remember what F. Benton said in Gleanings about the two kinds of bees in Carniola? Well, he said this: 'I never yet saw an apiary in Carniola that contained all steel-gray bees; many of the bees are yellow-banded.' The Ad'l bees I have were bred up from the yellow strain. Ad'l means, or rather signifies, superior, and as the natives consider the yellow bees superior to the dark bees, they call them Ad'l bees."

2. I'm not sure just how you would mean to use the zinc, but I see no reason why sheet-zinc might not be used for any part of a solar wax-extractor except the glass part. Very likely you mean the perforated part, and for that it ought to work all right.

York's Honey Almanac is a neat little 32-page pamphlet especially gotten up with a view to create a demand for honey among should-be consumers. Aside from the Almanac pages, the forepart of the pamphlet was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample for a stamp; 25 copies for 40 cents; 50 for 60 cents; 100 for \$1.00; 250 for \$2.25; 500 for \$4.00. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

The Premium offered on page 254 is well worth working for. Look at it.

United States Bee-Keepers' Association.

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., E. Whitcomb; Vice-Pres., C. A. Hatch; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GEN'L MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

Place and Date of Next Meeting:

Philadelphia, Pa., September 5, 6 and 7, 1899. Every bee-keeper is invited.

VOL. 39.

APRIL 20, 1899.

NO. 16.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

Don't Neglect Your Bees.—Winter losses have been severe, and there will be a tendency in the minds of some to be discouraged. But the wise bee-keeper will redouble his energies to take the very best of care of colonies that remain, treasuring as gold empty combs that are left. With the latter he can rapidly build up again, and there is no reason to believe that a good harvest may not be at hand, with fair prices.

The "Association" and the "Union."—A few weeks ago the matter of uniting the National Bee-Keepers' Union and the United States Bee-Keepers' Association was again brought up after a rest of about two years. We notice in a recent issue of the Modern Farmer and Busy Bee, Editor E. T. Abbott had this to say:

"There is an earnest effort being made to unite the United States Bee-Keepers' Association and the National Bee-Keepers' Union, as the aim and purpose of the two societies are the same. However, the matter seems to have reached a point where no further progress can be made until there is some radical change in the management of the National. General Manager Newman, of the National, in a letter to General Manager Secor, of the United States Association, makes such demands as a condition of the union as are never likely to be assented to by the general manager and directors of the United States Bee-Keepers' Association, and there the matter rests. The writer will say for himself, as a director of the last named society, that the union will never take place by his consent on the conditions set forth by General Manager Newman. The new

society has a work to do, and under the circumstances the best thing it can do is to go on and do it without any ill-will toward any other similar organization. Perhaps the time may come at some future day when the desired union can be brought about without any friction."

Of course, if there is to be a union of the two societies the initiatory steps must be taken by the National Bee-Keepers' Union. We were given to understand that its members would like to see a consolidation take place, else we would not have mentioned the subject again in these columns. We presume if five or six of the Union's members should request that a vote be taken at once upon the subject, such vote would have to follow.

But we are not advising at all. As we said in a previous editorial on this matter, the door is open for the Union to come into the Association whenever it decides to cast in its lot.

Nomenclature in Apiculture seems to be somewhat changeable, and, like so many other things in bee-keeping, varies with "locality." For example, in England "plumping" seems to be a term in common use, the meaning of which is hardly known in this country. Perhaps if this should fall under the eye of the esteemed Editor of the British Bee Journal he will tell us just what "plumping" means. Even no further away than Canada different terms are used. In the last number of the Canadian Bee Journal, page 518, occurs the expression, "take ten colonies of strong colonists;" and on page 521, "combs that had a light cap. . . . left the honey on cap." Will Editor Holtermann please give us the meaning, as there used, of "colonists," "light cap," and "on cap?"

New York's Foul Brood Law.—It seems that New York bee-keepers were more fortunate than those of Illinois, as we learn from the following that the New York legislature past the Foul Brood Bill:

The proposed Foul Brood Bill has become a law in New York. It is hoped that we shall be able to check the disease next summer. It was secured thru the efforts of the New York State Association of Bee-Keepers' Societies. Its success will depend upon the man who may be appointed inspector.

HARRY S. HOWE.

We congratulate New York bee-keepers on their success. The House Appropriation Committee of the Illinois legislature approved \$8,000 for destroying the San Jose scale, but refused to approve the expenditure of \$700 for exterminating foul brood. They also voted \$6,000 to the horticulturists, but not a cent for the bee-keepers. We hope soon to have the privilege of publishing the names of those who "turned down" the bee-keepers, so that when they come up again for election, voting bee-keepers may have a chance to "turn down" them. There was no good reason for ignoring the request of the bee-keepers, that the appropriation for the destruction of foul brood in this State be approved.

Apis Dorsata—An Explanation.—Dr. Miller sends us the following in regard to the way he was reported in the Chicago convention proceedings when discussing *Apis dorsata*:

MR. EDITOR:—On page 213 I am reported as saying with regard to *Apis dorsata*: "I am anxious that they should be brought here." Put in that unqualified way, that does not express my true sentiments. I am anxious they should be brought here if it is first known that they can be domesticated and kept under control. With my present light I am anxious they should be kept away. If they cannot be kept under control I can see no other result from bringing them here but to have them run wild and use up the nectar that our hive-bees should get. I have little fear as to that in the North, for I hardly believe they could

stand our Northern winters, but the result might be anything but desirous in the South.

It seems to me that it ought to be easier to domesticate them in their native region than to bring them here and domesticate them. Let the effort first be made where they are, and, if successful, *Apis dorsata* can be brought here; if the effort should be unsuccessful, *Apis dorsata* can remain in foreign lands, and this country be saved from another English-sparrow scourge. C. C. MILLER.

We agree exactly with Dr. Miller in the above—not because it is Dr. Miller who wrote it, but because we think his view in the matter is eminently sensible. It is always safer to be *sure* you are *right* before going ahead.

A Group of Canadian Bee-Keepers, to the number of 17, were taken in a photograph, and a full-page illustration therefrom graces the pages of the Canadian Bee Journal. They're a fine looking lot, making one wish for closer acquaintance.

Honey Advancing.—Gleanings says that *good* extracted honey is a scarce article, being 1½ to 2 cents higher than a year ago. A good article of comb honey could be bought a short time ago for 10 cents, and now "fancy" brings all the way from 12 to 14, and No. 1 from 10 to 13. There was one year, a good many years ago, when honey was so scarce that in spring it went up quite materially, but since then the rule has been that honey kept over till spring brought a lower price. There seems at present to be no question that *good* honey is a pretty scarce article, but it will not be so very long until the new crop from the South begins to come in.

Getting New Subscribers for the American Bee Journal ought to be easy work at this time of the year. The warm spring days will soon be here, when the bees will begin to hum again, and then their keepers will be interested in reading about them, and will want a good bee-paper. The Bee Journal, we believe, will just suit them.

From time to time we offer some excellent premiums to those of our regular readers who will go to the trouble of getting one or more new subscribers and send in the money. We hope that those who value the Bee Journal the most (our regular readers) will try to get their bee-keeping friends and neighbors to subscribe for it.

MR. FRED D. GIBBONS, of Orange Co., Ind., writing us April 5, said:

"The American Bee Journal gets better all the time. It is a welcome guest in our home."

THE FARM JOURNAL is 22 years old, prints 40 tons of paper a month, and is out of debt; it is cut to fit every progressive farmer and villager. Very well, see the offers on page 254. We will have the Farm Journal sent to your address for the balance of 1899 and all of 1901, 1902, 1903, and 1904—nearly five years—and it will get to you if alive anywhere on this planet.

R. L. TAYLOR criticised Dr. Miller for using the expression, "bring to a boil." The Doctor defends his usage by referring to the Standard Dictionary, the latest and by far the largest work of the kind ever printed. Mr. Taylor objects, saying no other dictionary makes any mention of "boil" as a noun in this sense (heating water). Dr. Miller is entirely right.—Stenog, in Gleanings.

A PATHETIC APPEAL.—The following poetical effusion won for its author, the Editor of the Rocky Mountain Celt, the prize of \$1,000 for the best appeal poem to subscribers to pay up their subscription:

"Lives of poor men oft remind us honest men won't stand no chance. The more we work there grow behind us bigger patches on our pants, once new and glossy, now are strips of different hue, all because subscribers linger and don't pay us what is due. Then let us be up and doing; send in your mite, however small, or when the snow of winter strikes us we shall have no pants at all."

We do not republish the foregoing prosy-looking poetry because we fear being pantsless by another winter, but thought it might help to remind some of our readers that their subscriptions were not paid up. We hope that all who are in arrears will remit promptly, and thus help to keep up the financial end of the Bee Journal—the very important end of the business—the "business end," as is sometimes spoken of the bee.

MR. F. GREINER, of Ontario Co., N. Y., wrote us April 9, wishing to make the following correction:

EDITOR YORK:—In your synopsis of my article, "He or She," on page 216, the meaning of a certain phrase is rather misrepresented. I do not wish to have it go that way, lest the German readers of the American Bee Journal might not think very highly of my conception of the German language. I did not say that the Germans nowadays call the queen-bee "kœnig" (king), for the intelligent, up-to-date bee-keepers do not. But it is a fact that this word "kœnig" has been used by the people just the same as the word "king" has been used here among English-speaking people.

In the case of the drone it is true that in the German language the drone has the feminine gender—"die drohne." F. GREINER.

EMERSON TAYLOR ABBOTT is no longer connected with the Modern Farmer and Busy Bee. We learn this from the following, which we received from Mr. Abbott last week:

"NOTICE.—I hereby cancel all offers to furnish the Modern Farmer. It has past beyond my control. Forced out because I objected to a certain class of advertisements.—EMERSON T. ABBOTT."

Mr. Abbott was making a good paper, and it seems unfortunate that his connection should be severed. But we are glad to know that he values principle above financial gain. There are too many in business who are just the opposite. Truly, the love of money is the tap-root of much evil.

THE MAN WHO SUCCEEDS.—The man who makes a success of an important venture never waits for the crowd. He strikes out for himself. It takes nerve. It takes a great lot of grit. But the man who succeeds has both. Any one can fail. The public admires the man who has enough confidence in himself to take a chance. These chances are the main thing after all. The man who tries to succeed must expect to be criticised. Nothing important was ever done but the greater number consulted previously doubted the possibility. Success is the accomplishment of what most people think can't be done.—C. V. White.

MR. W. T. RICHARDSON AND WIFE [of California], who spent several months in the East, have returned to his ranch and his bees in the Simi Valley. He reports better bodily health, but a sickly dry-weather feeling when he considers bee-matters. A goodly number of his 1,200 colonies are still on deck, but a good amount of feed will be necessary to carry them thru the season, provided it does not rain. Our conversation in this country is regulated by that proviso.—J. H. Martin, in Gleanings.

Langstroth on the Honey-Bee, revised by the Dadants, is a standard, reliable and thoroughly complete work on bee-culture. It contains 520 pages, and is bound elegantly. Every reader of the American Bee Journal should have a copy of this book, as it answers hundreds of questions that arise about bees. We mail it for \$1.25, or club it with the Bee Journal for a year—both for only \$2.00.

Biographical.

MR. A. C. SANFORD.

My father and mother came from Newtown, Conn., to Wisconsin in an early day. I was born in 1852, at Ashpunn, Dodge Co., Wis., and lived with my parents till 21 years of age. I was married to Irene Blair in 1874, and in 1876 we moved to Pierce Co., Wis., where I have since resided. I located in a heavily timbered section where the basswood grows tall, clovers abundant, and wild flowers are in profusion—a bee-keeper's paradise.

In my youth I loved bees and honey very much—especially the latter—and early I was eager to learn all about them. But father did not keep bees, and there were few kept in that locality, and those in a primitive manner. I longed to get a chance to try my hand at bee-keeping, but was obliged to be content with hunting bee-trees, and I learned in that way some of the habits of bees.

In 1876 I purchast my first colony of bees, paying \$7.00 for them; then my study with the bees began. I had the opportunity of being neighbor to a bee-keeper of considerable experience, and from him I learned many things.

My first season I got about 30 pounds of comb honey and one swarm. The first winter I lost the old colony, but the new survived. The following spring I purchast several colonies in box-hives, and experimented with them by transferring to frame hives. I procured the book "A B C of Bee-Culture," and with the aid of Gleanings and the American Bee Journal I was soon into the mysteries of bee-keeping. My wife used to say, "Albert, you spend so much time with those bees that they won't amount to much;" but the first thing she knew I had a fine lot of honey, and sold \$125 worth. Of course, after that I could fuss with the bees all I liked. And so I did. I kept on increasing till I had all I could handle (and sometimes more). I have never been without bees or honey since, and the American Bee Journal has come to me regularly ever since. So, Mr. Editor, I am nearly to the 25-year mark.

With the money I made from my bees I paid off the indebtedness on my farm, built a large brick house, improved my farm, and purchast a young herd of purely-bred shorthorn cattle in 1891, which have been kept on my farm, and have now increast till there are 30 head; also many have been sold.

This is giving the bees a good deal of credit, but any good, intelligent, industrious and honest person can do what I have done if he goes at it in the right way.

A. C. SANFORD.

nies, and if you have done it carefully so as not to rouse the bees in the least, you will be surprised almost into wondering what has become of the strong colony you supposed present. "It seems hardly possible such a vast host can so contract themselves that a gallon measure will more than hold a population you imagined would fill at least a half-bushel."

Selection for Work Rather than Color.—Speaking of the careful selection made by American breeders in rearing queens, Editor Holtermann, of the Canadian Bee Journal, says: "I doubt very much if there has been enough selection for honey qualities; doubtless there has been a great deal for color." Mr. Holtermann is quite right.

Open - Cornered and Split Top - Bar Section.—The Canadian Bee Journal mentions as a great and valuable reform the introduction of a one-piece section in which the passage for the bees runs the entire length of the top-bar and bottom-bar. The publishers of the paper have now introduced a section with a split top-bar, the foundation being held in place by being pinched between the two parts of the top-bar.

Queens Don't Lay at Will.—The elder Dadant, now in his 82nd year, yet one of the most vigorous writers in the French bee-journals, now appears on the scene in Gleanings in defense of large hives. In reply to the objection that in large hives queens lay so many eggs that they are soon overworked, and die, Mr. Dadant says: "The queen doesn't lay at will. The eggs come out when they are ripe, and the queen cannot stop their exit."

Honey Leaflets have been reported in Gleanings as not helping sales. But a recent number gives some favorable reports. C. R. Morts says, like a mustard plaster, they work according to the way they are applied. He says they're not as costly as labels, and are 16 to 1 better. F. Z. Buchanan says: "Fully half the customers to whom I have handed a leaflet along with the honey have asked, 'What's this?' lookt at the heading, and have been well along in the reading matter before I left."

Hanging Foundation the Other Way.—A "straw" in Gleanings is as follows: "W. S. Pender says that, instead of putting sheets of foundation in the usual way, he cuts the sheets in two and hangs it t'other way, and then it does not stretch. Does that mean it stretches more readily the way it has been already stretcht? [It is true, I think, that foundation stretches less when hung the opposite way to what it is ordinarily supported, than when it is fastened in the usual manner. We are just planning to reverse the hang of the cells on our rolls, because we know it will be an improvement to have them the other way.—Ed.]"

Fighting Upon the Introduction of a Queen.—Mr. Doolittle says in the American Bee-Keeper that instead of dead bees at the entrance being a sign that the queen has been safely introduced, it is a sign that she may have been killed, or, what is almost as bad, maimed for life. If bees fight over a queen, not one queen in ten comes out of such a fight as good as she was before. So it is desirable to have the queen caged till all fighting is over. Mr. Doolittle says: "I have known as many as a pint of bees to be killed when the cage was thus covered, yet the queen would not be harmed at all; but let half that number of bees be killed when the queen is among the fighting bees, and she will be materially injured if not spoilt entirely."

Big Yield of Pollen with Lessened Laying.—G. M. Doolittle says in Gleanings: "Just why the queens do not breed when pollen comes in so abundantly is a mystery I have never been able to solve, tho I have spent much thought and study over the subject. The nearest I can come to the matter is that, for some reason, the bees fail to feed the queen on the stimulating food usually given at all times when she is laying very prolifically, and all know she lays only as she is fed and cared for. When laying very prolifically we see bees offering the queen food every few minutes; but at these times when pollen is coming in so as to crowd the brood it is a rare thing that I see the bees feeding the queen. ... It is possible that a little very thin or diluted sweet fed at such times would have the desired effect, if fed just at night, this causing the bees to feed the queen, as it generally does at all times when so fed."

Queens in Diseased Colonies, that is, queens in colonies that have suffered from diarrhea in the winter, the Canadian Bee Journal does not consider as good as if the workers had remained healthy; and the introduction of fresh queens is advised.

Breeding in Midwinter is spoken of in Bee-Chat as a thing that commences regularly in normal colonies. That shows the milder climate of England, especially as compared with the northern States, and would be a surprise to Hon. R. L. Taylor, whose queens do not commence laying till April.

The Cluster of Bees Shrinks with Cold, according to Bee-Chat, in a way that is little realized by those who have made no careful examination. On some cold morning take a peep into a hive containing one of your strongest colo-

Root's Column

Bees Did Very Well.

My bees did very well last summer. It was the first year that I ever handled them. I am 13 years old, and tend my father's bees. We have 109 colonies. I had 60 swarms last summer, and I expect to do better next summer.

LAWRENCE BROYLES.
Socorro Co., N. Mex., March 21.

Banking Hive-Entrances with Snow

I have just been out shoveling snow up to the hive-entrances, as we put out our bees (one-half of them in the cellar), and it grew cold almost immediately, and they got no flight. It snowed more or less for three days, until we have had the deepest snow of the season—about one foot—and when the sun shines the poor bees fly out, and every one is lost, so we bank snow around the entrances, yet some push out, but I think the snow will soon go off.

MRS. L. C. AXTELL.
Warren Co., Ill., April 1.

Not a Colony Lost.

My bees came thru the winter in fine shape. I have not lost a colony, but some report heavy losses. I have now young bees cutting themselves out of the cells, and combs entirely filled with brood.

F. C. YENTSCH.
Lawrence Co., Mo., April 7.

All Wintered Well.

The valuable American Bee Journal has been a great help to me, and I can't get along without it. To-day has been bright and warm, so I got the bees out of winter quarters, and they had a glorious flight. I put in 11 colonies, and all came out brisk and lively. I hope some time to know a little of the much to learn about bees.

C. W. HEWITT.
St. Lawrence Co., N. Y., April 10.

Severe Loss in Wintering.

The past winter has been severe on bees. My brother told me that about 50 percent of them have "died out" in Salt Lake County, and other localities in the State. Pres. Lovey has lost all but 4 colonies.

H. W. DUDLEY.
Salt Lake Co., Utah, April 6.

A Long, Tedious Winter.

This has been a long, tedious winter for the bees in this country. I put mine into the cellar about Dec. 1, and they are still there, but I hope to get them out in a week or 10 days. There is plenty of snow on the ground at present. I expect to lose one-third of my bees. I put 122 colonies into the cellar, and will be glad if I have 80 the first of June. Some have lost all already. We had a good, average season last year, and hope for the same this year.

J. J. MARSHALL.
Vernon Co., Wis., April 7.

Sympathy Wasted on California.

So much sympathy being wasted on the Southern California honey crop for 1899, and in reference to Mr. C. H. Clayton's letter on page 184, where he says, "We shall make nothing this year." I feel in justice to Southern California to say that it will be well to let the creature die before you bury her. Now "shall" is a very strong word, and I, for one, think the word "will" would have been much more appropriate, as I consider the present prospects

No-Gob Foundation.

We Have it at Last.

It has been proven that wax in the base of ordinary foundation is not utilized by the bees, but is left there practically as it leaves the mill; and the result is, when drawn out into comb, the so-called gob, or fishbone, in comb honey.

Our New Thin-Base FOUNDATION

is exactly what its name indicates—foundation with a base as thin as natural comb, with heavy deep walls.

Fig. 7, herewith shown in cross-section from an actual photo, represents the new thin-base heavy-walled foundation running about 10 feet to the pound.

Fig. 13 represents the ordinary thin foundation with heavy base and scarcely any wall, about 10 feet; the heavy base, without modification, going right into the comb honey with very little change, and forming fishbone.

We have so far only small dies, and cannot afford to sell this product for less than 75 cents a pound.

Seven or eight pieces, large enough to fill 4 1/4 sections, 15 cents, postpaid; 24 pieces, prepaid, 40 cents.

The A. I. Root Company
MEDINA, OHIO.

SWEET CLOVER

And Several Other Clover Seeds.

We have made arrangements so that we can furnish Seed of several of the Clovers by freight or express, at the following prices, cash with the order:

BUY THE BEST.
If you want the best low down wagon you should buy the Electric Handy Wagon. It is the best because it is made of the best material; the best broad tired Electric Wheels; best seasoned white hickory axles; all other wood parts of the best seasoned white oak. The front and rear hounds are made from the best angle steel,

which is neater, stronger, and in every way better than wood. Well painted in red and varnished. Extra length of reach, and extra long standards, supplied without additional cost when requested. This wagon is guaranteed to carry 4,000 pounds anywhere. Write the Electric Wheel Co., Box 16, Quincy, Illinois, for their new catalog, which fully describes this wagon, their famous Electric Wheels and Electric Feed Cookers.

good, and if we get the rain which is now threatening, we will not be so nearly "out of sight" as some writers would picture us to be.

As to the extreme losses spoken of by many, I know not of others, but for myself I can say I have 96 colonies in fine condition out of 110 at the close of the season of 1897, and most of my losses, such as they were, were occasioned by my not requeening when they became queenless, as I thought it cheaper to save the combs and hive swarms, or make increase on them when a honey season did come.

I caught only one swarm last year, with possibly five or six lost, and have not fed any at all, and only kept a few from their more wealthy neighbors.

Now, do not come to California to produce honey, but take California for the seasons of 1898 and 1899, and compare with any State in the Union, and see how far we are behind them in proportion.

I am in favor of a consolidation of the Union and the Association.
L. L. ANDREWS,

Most of the Bees Alive.

I was afraid I shouldn't see more than half of my bees fly again; but most of them showed up alive to-day. **E. E. HASTY,**
Lucas Co., Ohio, April 10.

What is the Plant?

I have considerable curiosity about a plant that grows here in Washington Co., Fla. The bloom and seed-pods resemble garden-sage, and residents say that it is the same as California sage. If any of the bee-fraternity are familiar with this plant, and will tell us about it, they will confer a favor. The severe freezing of the past winter does not appear to have injured it in the least.

The roots of orange trees that were bankt up high with sand, are sprouting up; others

are not as yet. Orange-bloom honey will be a scarce product here the coming season. Some beautiful homes that were surrounded with these lovely trees are now nude and bare, and their owners discouraged.

A heavy rain is now falling, and it is to be hoped that it will not be followed by severe drouths similar to those of the two previous years. Rain will cause flowers to bloom, and bees may do better than they have done, even if the early bloom has failed.

Mrs. L. HARRISON.

Washington Co., Fla., April 8.

It Pays to Prepare for Winter.

Bees put up in good shape last fall are coming out in good condition, with very few losses; but those not packed and cushioned are just the reverse.

L. O. WESTCOTT.

Saline Co., Nebr., April 10.

No Loss Look Out for Starvation.

My bees have come thru the winter without loss. But very little honey is left. I am feeding all of them sugar syrup. I would advise all in this part of the country to look out for starvation among their bees, if they are not feeding.

M. S. TEAGUE.

Pike Co., Ind., April 10.

Hive-Entrances in Wintering.

I lost seven colonies out of 36 wintered in the cellar. Those in hives with bottoms similar to the Danzy, with wide sides up, wintered finely. Six of those I lost were in hives with tight bottoms and small entrances, and one had a 3/8-inch dovetailed hive bottom. Those with small entrances got damp, uneasy and moldy, while the others kept dry and clean, and are in excellent condition.

HERMAN L. GLOEGE.

Green Co., Wis., April 13.

In the Midst of Fruit-Bloom.

We are in the midst of fruit-bloom, and a glorious rain. It has rained more or less during the last nine days—over two inches have fallen. Bees are in No. 1 shape.

A. R. GURR.

Merced Co., Calif., March 24.

Bees Wintered Finely.

My bees have wintered finely with a loss of only one colony out of 59.

J. L. GRAY.

Stearns Co., Minn., April 10.

Taking Bees from Winter Quarters.

We expect to get bees out in about a week from this date. I have found three dead colonies out of 150, but expect to find quite a few more when we come to take them out.

WM. RUSSELL.

Hennepin Co., Minn., April 4.

Backward Season.

The season here is very backward. The winter has been so severe that many bees have frozen, thereby leaving many colonies weak.

C. C. PARSONS.

Jefferson Co., Ala., March 23.

Well-Behaved Bees.

Our bees did fairly well last season, considering it was a poor one. They are well-behaved bees, too, seeming instinctively to know their friends, and altho they occasionally give a sting or two, that is what bees of any kind of spunk are expected to do. But, on the whole, they are very gentle, and give no trouble because of savage tendencies. My hives face the east, and all have wintered in single-walled dovetailed 8-frame hives on the summer stands; but I have a shed built over them which is open the whole east front. Around each hive

are pieces of carpet. They have wintered in fine condition, and were out in large numbers one day last week.

We have not had much honey for sale for a year, but our customers have come again after having purchased once, for they say the honey is surely pure.

Mrs. M. B. MARTIN.
Menard Co., Ill., April 3.

Wintered All Right.

I have 35 colonies, which wintered outdoors with only a good covering of paper on the cover, and they get along all right. I have lost but one colony so far, and I am afraid they starved to death. I make my own hives and use the 10-frame Langstroth-Simplicity. I like it better than any other I have tried.

C. H. ANDERSON.
Christian Co., Ky., March 31.

Two-Thirds of the Bees Lost.

We have had a hard winter here. Bees have been dying with the diarrhea on account of the poor honey they gathered last fall. Every one in this locality lost 3 colonies out of 12. A good many bees that are left will spring-dwindle, for when there are no more than a double handful in a hive they surely will dwindle, we all know.

G. RENNERT.
Summit Co., Ohio, March 29.

Bees in Fair to Good Condition.

All's well. It now begins to look like spring, and everybody is hopeful of good times and a good honey-flow. The bees, as a rule, appear to be in from fair to good condition, but my! we have had a terror of a winter for snow. It has buried all records out of sight. There was said to be four times as much as last year. It is now hoped that we may have cool weather with little or no rain, so as to prevent floods.

E. S. LOVESTY.
Salt Lake Co., Utah, March 31.

Quite a Loss in Some Apiaries.

My bees seem to have wintered all right. I overhauled a few colonies early in March, and found lots of brood and some young bees, which shows that the queens must have commenced laying in the very coldest weather in February. There is quite a loss of bees in some apiaries. "They froze," they say, but of course they were not packed so as to keep dry.

GEO. SPITLER.
Crawford Co., Pa., April 6.

Wintered Poorly.

Bees wintered poorly in this locality, some losing one-half.

FRANK SNYDER.
Jones Co., Iowa, April 6.

Mr. Kipling's Life Saved

Convention Notices.

Illinois.—The Northern Illinois Bee-Keepers' Association will hold two sessions of its spring meeting, one at Mr. John Wagner's, near Beuna Vista, Stephenson Co., under the supervision of the Vice-President; and one at Mr. Oliver Taylor's, at Harlem, Winnebago Co., in charge of the President, on Tuesday, May 16, 1899. Every one is cordially invited. B. KENNEDY, Sec. New Milford, Ill.

Connecticut.—The annual meeting of the Connecticut Bee-Keepers' Association will be held at the Capitol, at Hartford, May 3, 1899. Waterbury, Conn. MRS. W. E. RILEY, Sec.

CHAS. F. MUTH & SON.

I wish to announce to my friends and patrons that I have this day sold to C. H. W. WEBER, of Cincinnati, my Honey and Bee-Keepers' Supply business, known for the past 38 years as CHAS. F. MUTH & SON. Mr. Weber will continue to push the Langstroth hive and everything pertaining to same; besides, he has secured the agency for Mr. Root's goods, and will sell them at his prices. I beg the customers of the old house, to whom I wish to extend my thanks, to continue their patronage with Mr. Weber, by whom I am sure they will be accorded fair and honest treatment.

MRS. ANNIE MUTH (Widow.) Cincinnati, Ohio, April 7, 1899. 15Atf

HONEY AND BEESWAX MARKET QUOTATIONS.

CHICAGO, April 8.—Choice grades of white, 12@13c; travel-stained and light amber, 10@11c; buckwheat and dark, 7@8c. Extracted, white, 7@8c; amber, 6@7c; dark amber, 5@6c. Beeswax, 20c. Stocks of white comb honey are about exhausted, and this is as it should be if a market is to be had for the expected large flow of nectar from the season of 1899. R. A. BURNETT & Co.

DETROIT, April 10.—Fancy white, 12c; No. 1, 10@11c; dark and amber, 8@9c. Extracted in fair demand without change in price. Beeswax, 25@26 1/2c.

Decreasing demand and the attempt to crowd sales have forced down prices on comb honey. M. H. HUNT.

NEW YORK, March 8.—Fancy white, 12c; No. 1 white, 10@11c; amber, 9c; buckwheat and dark, 6@7c. Comb honey is pretty well cleaned up now and we expect to dispose of the balance of our stock during this month. Excepting California there is not much stock of extracted on our market. Demand is fair at unchanged quotations. Beeswax, 27@28c. HILDRETH BROS. & SEGELKEN.

SAN FRANCISCO, April 5.—White comb, 10@10 1/2c; amber, 7 1/2@9c. Extracted, white, 7 1/2@7 3/4c; light amber, 6 1/2@7c. Beeswax, 26 1/2@27c.

Beyond a small jobbing trade, mainly out of supplies in second hands, there is nothing to record in the way of business. There are only moderate supplies, and these are mainly comb. Values are steady. It is too early to get definite information concerning coming crop, but it is not likely to prove large in this State.

BOSTON, April 1.—Fancy white, 13c; A No. 1, 12@12 1/2c; No. 1, 11@12c; No. 2, 9@10c; demand fair; no call for dark. Extracted, supply very light, good demand. White in 60-pound cans, 7 1/2c; light amber in barrels, 7c. Beeswax, very light stock, good demand, 29c. BLAKE, SCOTT & LEE.

KANSAS CITY, April 6.—Fancy white comb honey continues in good demand at 13 1/2@14c; choice white at 12 1/2@13c; dark, 10 1/2@11 1/2c. Extracted scarce at 6 1/2c. PEYCKE BROS.

CLEVELAND, March 9.—Fancy white, 13@14c; No. 1 white, 12@13c; A No. 1 amber, 10@11c; No. 2 amber, 9@10c; buckwheat, 8c. Extracted, white, 7c; amber, 6c; buckwheat, 5c. A. B. WILLIAMS & Co.

BUFFALO, April 1.—Little or no strictly fancy one-pound comb honey here. It would sell well at about 11@12c. Few lots of common, dark, etc., arriving, and sell at 7@8c mostly; some very poor at 6c. There is no extracted here; worth from 4 1/2@5 1/2c; extra fancy, 6c. Fancy pure beeswax, 30@32c; poor, 25@28c. BATTERSON & Co.

OMAHA, April 1.—Fancy white quotable at 13@13 1/2c; choice, 12@12 1/2c. Extracted, 6 1/2c.

Quotations are practically nominal, as there is no stock left now in receivers' hands, and dealers have also but very little left. There will not be a pound of any kind of honey carried over in this market. PEYCKE BROS.

MILWAUKEE, March 2.—Fancy 1-lb. sections, 13@14c; A No. 1, 12@12 1/2c; No. 1, 11@12c; dark or amber or old, 7@10c. Extracted, in barrels or kegs, white, 7@7 1/2c; dark, 5 1/2@6 1/2c. Beeswax, 25@27c.

Since our last report we have had a very good market for honey, and the demand has been very good for all grades, especially for sections of the best quality, and the demand is good now and small supply. We encourage shipments of best comb. Extracted, fair demand. A. V. BISHOP & Co.

Page & Lyon Mfg. Co.

NEW LONDON, WIS.,

Operates two Sawmills that cut, annually, eight million feet of lumber, thus securing the best lumber at the lowest price for the manufacture of... Bee-Keepers' Supplies...

They have also one of the LARGEST FACTORIES and the latest and most improved machinery for the manufacture of Bee-Hives, Sections, &c., that there is in the State. The material is cut from patterns, by machinery, and is absolutely accurate. For Sections, the clearest and whitest Basswood is used, and they are polished on both sides. Nearness to Pine and Basswood forests, and possession of mills and factory equip with best machinery, all combine to enable this firm to furnish the BEST GOODS AT THE LOWEST PRICES.

Send for Circular and see the prices on a full line of Supplies.

OUR MOTTO: WELL MANUFACTURED STOCK — QUICK SHIPMENTS.

Sections, Shipping-Cases and Bee-Keepers' Supplies

We make a specialty of making the very best Sections on the market. The BASSWOOD in this part of Wisconsin is acknowledged by all to be the best for making the ONE-PIECE HONEY-SECTIONS—selected, young and thrifty timber is used.

I ARISE

To say to the readers of the BEE JOURNAL that DOOLITTLE... has concluded to sell QUEENS in their season during 1899, at the following prices:

- 1 Untested Queen \$1.00
- 6 Untested Queens 4.50
- 12 Untested Queens 8.00
- 1 Tested Queen 1.50
- 3 Tested Queens 3.50
- 1 select tested queen 2.00
- 3 " Queens 4.00
- Select Tested Queen, previous season's rearing, \$3; Extra Selected, for breeding, the very

best, \$5.00. About a pound of Bees in a 2-frame Nucleus, with any Queen, \$2.00 extra.

Circular free, giving full particulars regarding each class of Queens. Address,

G. M. DOOLITTLE,

For Apiarian Supplies, address **LEAHY MFG. CO.,** Higginsville, Mo., 1730 S. 13th St., Omaha, Neb., 404 Broadway, E. St. Louis, Ill.

Eastern Bee-Keepers!

Furnishing bee-keepers with practical appliances to use in producing honey in marketable shape so they will receive the highest price for it, is our principal business. If you are in the EAST you will make a great mistake if you send WEST for your Supplies, wait several weeks, and pay a big freight bill, when you can get them in a few days, at as low a price, and less freight to pay. Our Catalog will explain. It is Free. THINK IT OVER. We carry a large stock and the quality is of the best. We also own two Apiaries and sell

ITALIAN BEES AND QUEENS.

These Apiaries are run for HONEY and pay well, as the bees are hustlers.

Untested Queens, 70 cents; 3 for \$1.80; 6 for \$2.70.
Tested Queens \$1.00 each.

I. J. STRINGHAM, 105 Park Place, New York, N. Y.

BEE-SUPPLIES!

We have the best equipt factory in the West. Capacity, one carload a day; and carry the largest stock and greatest variety of everything needed in the apiary, assuring BEST goods at the LOWEST prices, and prompt shipment. Illustrated Catalog, 72 pages, Free.

We also manufacture Tanks of either wood or galvanized steel, all sizes, any form, for all purposes. Price list free.

Address, **E. KRETCHMER, RED OAK, IOWA.**

CONTRIBUTED ARTICLES

Concerning Bee-Moths and Robbing.

BY HARRY S. HOWE.

DURING the past few weeks I have attended several bee-conventions in different parts of the State.

Among the things that struck me as worthy of note was the number of people who had questions on the two subjects—bee-moths and robbing. Generally the man who was interested in one also had some questions on the other.

And not less curious to me were the remedies proposed. One man advised that the combs to be kept from the ravages of the moth be first soaked in brine, then dried and packed away. When they were to be used again they were to be soaked in fresh water to remove the salt, and then dried again!

Some years ago I bought out a bee outfit. The former owner wintered the bees in a double-walled house. Some time during the previous winter he died, and the family, being afraid of bees, opened the door, but left those bees just as they were. When I got them later in the season there was a sight. The rats had eaten the lower tier of hives about all to pieces. Some of the bees had moved out and taken up their abode in the corners of the room. Others had succumbed entirely, while 15 colonies still held the fort in their hives, and the moths—well, there was a great chance for missionary work. Yet in a season or two, without any special treatment, there were no moths to be seen. And the bees were not Italians, either.

All the precautions necessary to keep my large stock of extracting-combs even at that place are to space them one less to the hive than they are used in the summer, and then leave them where they will freeze during the winter.

The moth passes the winter usually in the egg-stage, and a good, solid freeze will kill those so in the spring there are no worms to eat the comb.

There are usually two broods during the season, one in the spring, the other during the fall. It takes about three weeks for the larva to mature.

Another point in the safe keeping of combs is the presence of pollen or dead brood. The larva of the moth cannot live on wax alone, they must have some other food. Now, combs used for extracting seldom have any pollen or other nitrogenous food for the worm. The combs which are in hives where the bees have died are the most liable to their attacks. How to protect them brings me to the second of those two questions—

HOW TO PREVENT ROBBING.

We used to think that we must not let a bit of honey be exposed when the bees were not storing honey or we should have trouble from the robbers, but now we do about as we

please in that regard; that is, always keeping in mind certain laws.

When the bees start to rob a place, if we can make them think they have got it all, there will be no further trouble, while if we cover up or take away the honey they will keep on looking for it.

Now for my method of feeding the bees, and at the same time caring for the combs that are likely to be troubled by the bee-moth:

As soon as the bees begin to work in the spring, I go around and take out all the dead ones and store the honey and combs in the honey-house. Then I put out one or two hivefuls of it somewhere at one side of the apiary, leaving the entrances so the bees can get in and carry away the honey. As fast as one lot is carried away I put out more, as long as I have more to put out. Then I go thru the hives and take out the heavy combs, replacing them with the ones first cleaned out, letting them carry this honey back in turn. This I keep up clear to the time of the honey-flow.

No self-respecting moth will stay in those hives that are used for feeding; things are too much stirred up, and

J. L. Hubbard. See page 265.

the combs go into good, strong colonies often enough to discourage them if they tried it. If we can keep the spring brood of worms from maturing, we shall have to wait for more until our neighbor sends them to us in August again.

As to robbing, the only time I ever see any is at the last extracting, after the honey-flow stops in the fall, and

not then unless we are a little too slow in getting over the yard. I mean bees trying to rob one another. I usually give them something else to think about at that time.

As fast as the combs are extracted they are spaced and piled crosswise of one another so the bees can get at them freely. Soon the bees find that there is honey to be had in the back part of the honey-house, and they start in to clean those combs. By the time the last one is piled away there is a scent like the one Ernest Root so graphically described after one of his visits to W. L. Coggsball, but there is no robbing in the yard.

Perhaps if one works slow enough the bees might get started on colonies that were opened any time when there was not a honey-flow, but life is too short and honey too cheap to spend that amount of time over any one bee-hive.

I cannot better sum up the question than by quoting a remark made at dinner at a recent bee-convention: "No good bee-keeper is troubled by bee-moths or robbing." Tompkins Co., N. Y.

Methods of Introducing Queens.

BY FRANK COVERDALE.

SOME years ago I sent to a Massachusetts queen-breeder for six queens, and they were to be introduced according to his plans, and if any failed to become safely introduced the dead would be replaced by living queens. His instructions were to remove the old queen from the hives that were to receive the new stock; and bare of the candy, at once lay the cage over the frames and close the hive for five days—a thing which I did, and found only one queen that had been accepted.

Two or three years later I received an albino queen from an Iowa breeder, but this time I made the colony queenless that was to receive the queen 48 hours before introducing, and lost my queen. I could not understand why it was that these queens, coming from a distance, were rejected by my bees when I had no trouble in introducing my own stock among my own. May be some one can tell.

I sent South last spring for 50 queens, and when they arrived all were laid on the shelf, and 48 2-frame nuclei were made, and all shut up tight with wire-screen until 48 hours had past, then the 48 queens were laid on top of the frames as before, and every single one was accepted. All had started cells in abundance, but when the queens were set free all cells were destroyed. I didn't wait five days, either, to see what was going on, but took a look at any of them at any time I chose. The remaining two were introduced in full colonies, but not confined with equal safety. I think I would not be afraid of introducing any number when done as above. Tho others may have plans that work equally well, I am not afraid of this plan in my hands. Jackson Co., Iowa.

Strawberries and Bees for Women—Propolis. Etc.

BY MRS. L. C. ANTELL.

I THINK strawberries as a side-issue go well with bee-work for women. The question is often asked, What other work can women do besides caring for bees, as honey sometimes fails? Strawberries never fail with us.

In the first place, she needs to dress suitably for out-door work. This is of the utmost importance, for if she tries to dress as she does for house-work, her health will suffer. She should have a good, strong pair of boy's boots, warm underclothing, and a dress of strong material like gingham or flannel. I like flannel for cool weather, as it does not catch the dirt like cotton goods, and always looks neat.

Most farmers' wives expect, and almost always have, lettuce, onions, beans, etc. Let them *determine* to have strawberries, also, and they will have them in abundance. I do not speak from theory, but from practice. I know they are not so hard to raise as most people think, and what a bountiful crop they do repay, if we only know how to grow them; and then they are so appetizing, so luscious, coming so early in the spring before other fruits and most vegetables are ready for use.

STRAWBERRIES IN THE BEAN-BED.

To make a beginning send 25 or 50 cents to a nurseryman, or some one who has good plants for sale, and get half in staminate and half in pistillate plants. Ask him to send you his best kind for your locality and for fertilizing.

As soon as received open them and put the roots in thin mud in a basin, but don't get the leaves muddy.

Now towards evening set these out in the bean or radish or lettuce bed, or early cabbage bed. Set them in just deep enough so the ground will be level around them, and the roots well spread. As these plants grow to need the room, pull out the lettuce, radishes, etc., and give them room. Cut off all the flowers that bloom on them the first spring, for if they should fruit the first year they would not amount to much—would be small and hard.

Keep all the runners cut off until the first of July, then after that time set the runners by spreading them out in all directions from the main plant, like the spokes of a wagon-wheel. What is meant by covering up the runners is to put a little fine dirt on the end of each runner, and press it into the ground so it will take root.

The reason I speak of planting the strawberries in the beds of the vegetables is because the ground is generally in good condition for planting the vegetables, and will be likely to be kept mellow the first part of the season; but if the strawberries can be given a bed all by themselves, all the better; and if the ground could be gotten ready in the fall, by being made very rich with barnyard dirt, and plowed or spaded in, and the ground made very mellow, all the better. Then plant the strawberries as early in the spring as you can get the ground ready, as early planting is always the best. Now, do not think this too much work for you, as it is no more work to raise strawberries than flowers, and they pay ever so much better. Besides, the strawberries have beautiful flowers upon them, almost as beautiful as any raised in the flower-bed; and then, the plant itself, when raised on rich ground, makes a fine foliage plant. If I could find no other room I would plant it as a border along my flower-bed, or have that unsightly back yard spaded up and strawberries planted there. They will bear considerable shade and yet fruit some, but will not fruit much if continually tramped over by children or chickens, but will look ever so much better than weeds.

Strawberries for profit should be fenced away from chickens, the ground kept very rich and mellow, covered slightly in winter with straw or other covering, and good plants taken from beds that have not fruited, both pistillate and staminate varieties. They will pay largely for work on them, and it may all be done by women at times when the bees do not require attention, by getting the bees ready for white clover honey before strawberries are ripe.

If one succeeds in raising more strawberries than are wanted in the family, there is always a good sale for them, people coming to your doors for them at good paying prices; or, if you have no time to pick them yourself, they will pay by letting others pick and pay for them at a reduced price. But it should be understood that no children are wanted to trample the vines, and if others besides yourself pick them they should be kept in narrow rows.

The early, such as Mitchell's Early and medium kinds go best with bee-work where many are raised. The latter ones, like the Gandy, do not ripen until swarming-time, but it is so nice to have strawberries even in swarming-time for table use, as they can be picked morning and evening, and do not have to be cooked, and if one has a large dish of strawberries and a plate of honey, bread and butter, many a meal can be made out when there is little time for cooking in swarming-time.

If one raises berries for market, of course the quart boxes should be made before wanted, in leisure time in the winter, just as bee-work, such as getting sections ready for the bees, should be done in winter-time, or before wanted.

PROPOLIS AND WHITE CLOVER.

Last spring I took time when clipping queens' wings and scraped the inside of our hives and edges of combs very clean and carefully. I supposed it was nearly all propolis. I had nearly a half-bushel when I got around with all the 160 hives. I thought it not worth saving, but did not want it thrown upon the ground to stick to the bottoms of our shoes, so I thought I would throw it in the sun wax-extractor, and was much surprised to see a nice cake of beeswax when all was melted in a day or so. It was not so light yellow as honey-comb would be, but looked like dark beeswax with a greasy appearance, but softer than beeswax, and smelt of rosin. I think it would make a good ointment, but would not do for foundation, even for the brood-nest.

Bees are flying nicely to-day (March 9). Just after the severe cold weather I examined all our bees that were out-of-doors, and all were alive, and apparently wintering well, altho they have not had a flight for a good while. I threw out many dead bees. One colony was injured by the mice

getting in and working in the chaff which clogged the entrance; nearly half the bees were dead in the hive. I think to winter out-of-doors in this climate bees should always have chaff or some such material packed around them on all four sides and on top, and raised from the bottom-board an inch or so, as was Moses Quinby's method of out-of-door wintering. We follow his plan, and find it most successful.

White clover does not seem nearly so abundant of late years as it used to be years ago in this vicinity. The roadsides sometimes used to be white with it, which has not been the case of late years. We used to think it was the dry weather that killed it, but it has been wet enough for other crops for two years now. Dry weather in the winter, and freezing and thawing, seem to have it out and kill it.

Warren Co., Ill.

Spraying Fruit Trees and Bushes.

BY F. A. SNELL.

A GOOD deal has been said and written on this important subject, and yet there are some who do spray at a time when all informed persons and all writers say it should not be done. That time is during the blooming period. All who have given the matter intelligent thought know that spraying at this time is worse than useless in destroying the codling-moth, as the eggs have not at this time been deposited, for there is no place to deposit them. The eggs are not laid by the female moth until the fruit is formed, and the eggs are then deposited in the blossom-end of the apple. It is thus evident that spraying earlier is of no value, as there is nothing to destroy in this direction.

Much harm will result from spraying while the fruit is in bloom. The busy bee—the best friend, and most useful one, the fruit-grower has—while in search of honey and pollen will be poisoned from that thrown upon the blossoms by spraying. In this the fruit-grower is deprived of the great fertilizing agent—the busy bee—for while gathering food for its own use and the rearing of young, it carries the pollen-dust from blossom to blossom, thus fertilizing them, without which very little fruit could be secured. The bee-keeper also suffers from the great loss of bees, which means to him depleted colonies, and as a result of this perhaps little or no increase of colonies, and no surplus honey, when had it not been for the stupidity of the one who did the spraying while the fruit was in bloom, a good increase in bees and a fair to good crop of honey might have been secured by the apiarist.

This matter of spraying at the right time is a very important one, and should be kept before the people who do not all yet seem to understand its importance, until the public is well-informed.

According to the best authorities I have read, there is no fruit that should be, or need be, sprayed until out of bloom, when apples, plums, cherries, gooseberries and currants should be sprayed to destroy the insects or worms which prey upon them. Spraying with the proper materials soon after the bloom is over will largely destroy the fruit depredators, but it is well to give two applications, the second one being given about one week after the first.

I have used paris green for a good many years, and have found it to be very effectual in destroying every insect or worm that feeds upon the fruit or foliage of the trees or bushes. London purple is also a good insecticide, but I have not used this, as paris green has pleased me so well.

Leaf lice have appeared the past few years on the leaves of apple and plum trees, which we spray with paris green to good advantage.

For currant-worms, which attack our currant and gooseberry bushes, we have used both the paris green and white hellebore, and rather prefer the latter, which may be applied in the form of powder or liquid. A sharp watch should be kept of the bushes, as the worms come up from the ground and do rapid work, first working on the lower leaves. They begin their work when the leaves are about one-fourth grown. The poison would better be put on the first time a little in advance of the worms, and thus nip them at the start. Two or three applications at intervals of five or six days will suffice, and leave the bushes and fruit in good condition.

Spraying to destroy fungus that works on or attacks the leaves of fruit-trees and numerous others, as well as bushes, potatoes, etc., is also an important work which should be done. The first application needed for this is at the same time at which we should spray for the codling-moth and the other fruit enemies which begin their work about

the same time. According to no less authority than Prof. Burrill, of our State University, the spores that have until recently been supposed to live over winter on the twigs of trees do not do so, but instead live over winter on the leaves that drop to the ground, and there remain until spring weather ripens them, when they float in the air and later attack the leaves of trees. Now the destruction of the two may be accomplished at the same time by using the poison and a fungus destroyer, the two being mixt together and applied with a good sprayer a few days after the trees are out of bloom. A second application should be made about one week later, or in a little less time, rather than later.

The fungicide or preventive is composed of sulphate of copper, three pounds, to be dissolved in eight gallons of water. In some convenient vessel two pounds of lime in three gallons of water is slackt, and when cool is poured slowly into the copper solution, at the same time keeping the liquid well stirred so that a thoro admixture may be effected. To this I added four heaping teaspoonfuls of good paris green, and mixt thoroly. Before filling the sprayer the liquid was well stirred each time, so that the work would be more effective. No sediment should be put into the sprayer. The quantity mixt can be varied to suit the needs of the user. The proportions should be kept about the same.

No fruit or other tree or bush can remain healthy and produce good fruit unless the fruit and leaves are kept in good condition. The leaves are the lungs, and must be kept free from preying enemies, the same as should be the fruit. Wormy apples, stung plums, wormy cherries, currants and grapes may be reduced to the minimum by spraying, which is the only way that the best fruit can be preserved. This with good culture and care in other directions will give us good fruit in abundance.

From the fact that the spores live over the winter on the fallen leaves, as Prof. Burrill says, it is very evident that all leaves should be burned during fall, winter, or very early in the spring, so the fungus spores may be destroyed.

What has this to do with the apiarist? some may ask. It is this: In order that our bees may reap the great benefit from an extensive fruit-bloom it is essential that our fruits of all kinds be kept alive and in abundance, which can only be secured by preserving fruit-trees and bushes in a healthy and vigorous condition, and bear, to encourage still further planting. With no fruit-bloom our bees could not be strong enough to secure any surplus honey from white clover, or but very little at most. One who has not tried it would be surprised at the amount of such work that may be done in a day, or even a few hours, with suitable and cheap conveniences.

Carroll Co., Ill.

The Afterthought.

The "Old Reliable" seen through New and Unreliable Glasses.

By "COGITATOR."

A SEEMINGLY HILARIOUS CONVENTION.

Inauspicious the opening of that Chicago convention! First they put up the Beers, and then somebody called for Moore; and then they all gave willing ear to a foul subject. Mr. Taylor himself might almost be suspected of hob-nobbing with Beers, when he leaves us in doubt whether foul brood *smells* like a bad case of dysentery, or only that the looks around the entrance of the hive suggest it. But he tells us something of sober value when he says for us to tinker with foul-broody bees only when no bees whatever are on the wing. (Page 101.) 'Tater doesn't believe that dysentery and foul brood smell alike; but his experience is scanty. Doubtless in early spring the same colony sometimes has both diseases at once, to the confusion of non-expert noses.

DON'T CROWD VILLAGES WITH BEES.

On page 181, Dr. Miller is admirable in willingness to yield the monopoly of the honey-trade, that the fertilizing office of the bee may be carried on everywhere, to the general good of the human race. But the logic is not quite

faultless that would insist on keeping bees inside every village for that reason. Our villages are not so large but that outside bees can cover them. We err a little (the rest of us, not Dr. Miller) in trying to "spunk up" our spunky brethren to persist in disregarding protests, where families live right adjacent, and want their little children to play out-doors without being stung. Move the bees a short distance, into a vacant vicinage, before the irritation grows to an ordinance of expulsion.

NUMBER OF BEE-KEEPERS IN A COUNTY.

I don't know whether the 150 bee-keepers of Cook County have occasion to say, "Teacher, they're crowdin' here," or not. A survey township of suitable territory would have space for nine apiaries, and allow four square miles to each. Now add as many more who only want to keep just a few colonies, and we have 210 to the county. Cook County on the map looks like 20 townships.

A FEW OF MR. DADANT'S SUGGESTIONS.

C. P. Dadant, on page 164, gives us the new phrase, "experienced novice." Well, yes, that's him—handles his bees as a lussy baby handles a kitten—really more for the sake of handling them than for the nominal object—and the inexperienced old-fogy's bees win the race. Mr. D. also formulates a handy new rule: As many combs as they can cover, and two more, for a colony at spring examination. I guess that's a good rule, altho I don't quite live up to it. I seldom take out combs unless the bees are quite weak. In one thing I think a warning is needed, where Mr. Dadant says that a colony given a comb of sealed honey will not show excitement and attract robbers—*some* danger, I fear, when the colony is weak, and also on short allowance. On page 180, he makes a good hit in saying that thin food in spring, if not unreasonably thin, will stimulate more, and save many trips for water, which often cost heavily in bee-life.

LOOK OUT FOR A "HOT TIME."

In Dr. Miller's excellent department (page 166), he let slip one incautious expression that may do harm—where he says pour the syrup "pretty hot" into the combs you are filling to feed bees. As I have "been there," I have a right to protest that one needs to look quite a little odd or he will damage combs by softening the wax. With hot syrup in it, "first you don't know" your comb tumbles right out of the frame. A *little* hot syrup can be put in the middle of a tough old comb; but even thus the ends of the cells are destroyed by a touch.

THE "IMPROVED SPELLS" GIVE "TATER A BAD SPELL."

And so (as per page 169) we are to have a new batch of improved spells. "Tater feels an interest in this matter; but personally he thinks he is too odd to get rid of his orthographical prongs now. Luckily he is not too odd to find fault—and he finds some with that new word "thoro." Either let it be, or spell it "thuro." Don't rile us with what impresses the eye as a bran new word, with its first vowel masquerading in the place of another vowel. Of course, sometime in the future it will have to be changed again—just a wretched case of cutting off the dog's tail at two times.

A QUARTET OF "AFTERTHINKLETS."

Three year's experience with artificial heat in wintering, and not a colony lost, is valuable testimony. Thanks due to A. E. Bradford, page 171.

Mr. Bingham didn't say directly that he winters his bees out-doors, in northern Michigan, but it sounds so; and if such a big hole in a hive as an entrance 7, x 12 inches results well, that is valuable testimony. Page 173.

It seems I did Mr. Hart an injustice. He was seeking to doctor some honey, but only to make bee-food of it. Glad to correct.

Three-story 15-frame Langstroth hive, just the thing to convert the world with, eh? Well, here we are, Mr. Riker, all sitting in the "rowdies" corner, eating peanuts, and waiting for the services to begin. Page 194.

MORE ABOUT FACING HIVES.

Mr. Reitz, on page 189, strikes another consideration of some importance on the hive-facing question. Sometimes colonies faced west will get a pretty good flight in winter when those faced east got none. And here's another item I would add: When one or a very few hives face south or west, and all the rest east, and when there comes a winter day that they all fly, the first-mentioned hives may get very

strong in bees *at the expense of the others*—bees stay out till the east doorways are shaded and cold, and then seek a warm, lively entrance to go into. As bees usually behave as free commoners in winter, they can easily do this. And if it happens that the only hive faced a warm way is one the keeper is trying a wintering experiment on—just you hear him shouting what a valuable discovery he has made.

THE BELL ROBBER-BLOCK.

G. W. Bell's robber-block, page 188, will very likely be of some use in cases where the assailed colony has spunked up during the night. Its strong point is that the robbers think the proper place to get in is on top of it. But of course they'll find the new route unless the bees inside defend tolerably well.

THAT GERMAN CASE.

On page 186, paragraph 12, that German case of a great swarm that yielded less surplus per pound of bees than swarms less than half as large did is important *if valid*. I think it common for the old bees of mixt swarms to half of them go home during the first few days after hiving (don't like the miscellaneous company), and unless the managers of this experiment assured themselves on this point the result has no special significance.

CONSOLIDATE FOR BETTER LOOKS.

It will *look* better to have the Union and Association consolidate, and page 184 reads as if the prospective wedding was approaching—Niagara Falls condition—"nuthin' to hender"—or at worst only a few broken bones and delayed love letters.

HONEY-DEW ON THE GRASS.

I like to see a man fight well on a losing side; therefore I incline to cheer S. W. Maxey (page 178) in his plea for real honey-dew right from heaven. I shall be a glad and easy convert if I can *see* a little of this—but at present I apprehend that the sweet on the grass was direct exudation, or possibly from wounds made by grasshoppers, and so practically the same as stubble-honey—or what's to hinder its being insects down on the sod, and firing the nectar up *a la* Theilmann? At any rate, honey on the grass will have to be allowed the name of honey-dew.

PROF. COOK BALANCED OFF ON HONEY-DEW.

Mr. Cowan is one of the first-class authorities, and if he is convinced that honey-dew is sometimes a direct exudation from leaves, without insect agency, Prof. Cook is balanced off—in fact more than balanced off—as one competent witness, holding actual and direct evidence, weighs more than ten equally good men who hold merely the *absence* of evidence in situations where evidence might be looked for.

MR. THEILMANN'S FIRE-ENGINE PLAY.

Also Mr. Theilmann's case of honey from the nodes of birch leaves—we shall have to allow that to be called honey-dew, too, as it gets spattered around upon the leaves. We are glad to hear of its excellent quality. (Say, not a great while ago I was on the side which appears to be licking its adversaries out. Prof. Cook, behold your recent convert's back-sliding under the loam). Mr. Theilmann's experiment with the aphides, making them eject by having some one jar the tree, and looking toward the sun to see the sprays, and especially the surprising distance they can play fire-engine, are valuable contributions to our knowledge.

THAT EXPERIMENT IN PRODUCING EXTRACTED HONEY.

And now I haven't half the room left that might be well devoted to Mr. Davenport's experiment, on page 179. Probably it would not turn out the same all years and all locations. Right glad am I to see that the result favors neatness and propriety. To let the queen run "amuck" thru all the combs decrease the surplus instead of increasing it—to this time, 500 pounds, 175 pounds, 150 pounds; the better score being where the queen was kept in one story. As to non-swarming, the result is the other way, to be sure; but then many of us are not prepared to give our colonies each three stories of finish comb, anyway; and with less than that, swarming is only decrease a little, not prevented. Rearing a great host of bees too late to be of any use, is credited with the above decline of surplus.

COGITATOR.

The Premium offered on page 254 is well worth working for. Look at it.

CONVENTION PROCEEDINGS

Report of the Vermont Bee-Keepers' Convention.

BY M. F. CRAM.

The 24th annual convention of the Vermont Bee-Keepers' Association was held at Middlebury, Feb. 23 and 24, 1899. The meeting was called to order at 1:30 p.m. by Pres. R. H. Holmes, prayer was offered by O. J. Lowrey, and the minutes of last meeting were read and approved. The following committees were appointed by the chairman:

NOMINATIONS—A. E. Manum, W. G. Larrabee, and J. I. Clark.

RESOLUTIONS—W. H. Bristol, H. L. Leonard, and G. W. Fassett.

Next in order was the following paper by W. G. Larrabee, on

The Production of Extracted Honey.

Bees run for extracted honey should be watched more closely in the spring to see that they do not get short of honey, for I find that I am more liable to be deceived on the amount of honey in the hive, as they will fill all of the combs for perhaps two inches below the super, and the rest of the comb will have no honey in it at all. This is not an invariable rule, but it is more liable to be the case when run for extracted honey than for comb.

I use 10 Langstroth frames in the brood-chamber, and a division-board; and 10 Langstroth frames in the upper story without a division-board, spacing the frames a little farther apart. This allows the bees to lengthen the cells a little, and they can be uncapped more readily, and more honey can be put into a frame.

I put the upper stories on before the bees begin to get honey to amount to anything, and before white clover opens, sometimes in fruit-bloom. I do this in order to give them plenty of room before they begin to get the swarming-fever, and do not let them get their hives too full before extracting.

I extract as soon as the combs are about one-third capped, and in most years honey will not sour if as ripe as this, but at the close of the season I like to let them cap the combs nearly all over, as I think it gives the honey a better body, and is less liable to sour. I use queen-excluders on all hives, and could not get along without them.

When the honey is ready to extract, I go to the yard toward night and put the bee-escapes on the hives that need extracting, and the next morning they are usually free from bees. (I say *usually*, for sometimes an escape will not work, or something of the kind.) I am then ready to extract.

I have an uncapping-tank that allows the honey from the cappings to drain off at the bottom, and quite a lot of honey is saved by so doing. I have a 30-gallon can with a honey-gate; I tie a cheese-cloth strainer over this, and let it sag down enough to hold two large pailfuls of honey. As fast as it is extracted I pour it into this, and allow it to drain thru at its leisure, and it will usually run thru as fast as I can extract it. From this large can it is drawn off into 60-pound cans, of which I am careful to have enough at the yard where I am extracting, and it is then ready for market.

The empty frames are returned to the hives after I am thru extracting—usually towards night and after the honey-flow is over. They should never be returned at any other time except toward night, for if it is done in the morning, or middle of the day, it will excite robbers to such an extent that you will not care for a second dose.

I always put the empty combs back on the hives at the close of the season, and leave them there until cold weather comes, as the bees can take better care of empty combs than I can. But if this is done, queen-excluders should always be used, or one will be likely to find the bees all in the upper story, and the honey for winter all in the lower story.

As I have said before, great care should be taken not to be deceived on the amount of honey in the brood-nest in the fall. I have opened many a hive that apparently had plenty of honey, but upon closer examination there would not be more than 20 pounds, and this is not enough.

There is nothing to be said about winter packing, for they are packed the same as those run for comb honey.

I do not have very much trouble with swarming about all that I do have is from some very strong colonies that get their upper story too full before I get around to extract. I usually give such colonies several empty combs a few days before I extract, or divide them. About all the increase I have at this yard I get by dividing.

I have been surprised to see the difference there is in different seasons in regard to the average amount of honey produced by bees run for comb and for extracted honey. Some years they will produce but very little more run for extracted honey than for comb honey, but last year they produced more than twice as much extracted as comb. This is why I have made such varied statements in past years in regard to the relative expense and profit of bees run for comb or extracted honey, and I am not yet able to say which pays the better.

W. G. LARRABEE.

Prof. George H. Perkins, entomologist at the Vermont Experiment Station, then gave a lecture without notes on the relation of other insects to bees. He exhibited a German collection of bees, and different kinds of combs, showing some of the diseases of bees as they would appear on the comb, all under glass. Also a collection of the forest worm that has wrought destruction to some of the finest maple orchards in the State. It strips the apple-tree of both leaves and fruit, also the basswood, so that it yields no honey. Certain insects were very closely related to the bee, especially the bee-moth. Every insect which injures the flowers injures the bees. Things do not happen by chance—there is a reason for everything. He would make no promises, but thought we had seen the worst of the forest worm, as the Ichneumon fly was destroying large quantities of them. Out of 200 cocoons that he examined at one time, only 30 developed, or 15 percent. The eggs on the trees were laid in cylindrical form, both edges of the cluster being very nearly true around the twig, while the common tent or apple-tree worm laid its eggs more irregularly, tapering off more or less each way. They could be cut off from small trees by taking a long, slim pole with a knife in the end of it. People were learning that cross-fertilization was necessary. Bees would still be a blessing if they never gather honey.

The Professor was asked a large number of questions, which were answered in a very pleasant and satisfactory manner, after which he was tendered a rising vote of thanks.

SPRAYING FRUIT-TREES.

Mr. Boardman had sprayed 75 trees with 60 gallons of water and 1½ pounds of paris green. He secured 150 barrels of apples. He sprayed the first time just as the buds began to open; the last time just after the blossoms had fallen.

Mr. Isham sprayed six times, and got no fruit.

Mr. Manum sprayed just as the buds opened, sprayed again just as the leaves came out, after that every week or ten days, but didn't get much fruit. One of his neighbors did not spray at all, and got a very heavy crop of fruit, so much that he had to prop up the trees.

Prof. Seely, of Middlebury, then gave a short talk very complimentary to apiarists, as well as instructive. He said he had learned that bee-keepers were very observing, and he had learned very much listening to them at their meetings. He first became interested in entomology in studying the apple-tree caterpillar. They were destroyed by the Ichneumon fly.

Mr. Crane said a heavy late fall of snow in the spring would destroy the forest worms and tent caterpillar; and said there was a difference in the time it took for the eggs to hatch of the forest worm and tent caterpillar.

It was decided that the president and secretary be appointed a committee to confer with the same officers of the Horticultural Society, to see if they would hold their next annual meeting together.

A report of the members present was then taken: Number of colonies in the spring of 1898, 1,779; number in the fall, 1,994; produced 80,000 pounds of comb honey and 6,000 of extracted.

QUESTION—Is it profitable to feed just before the honey-flow? **ANS.**—No one thought it was.

EVENING SESSION.

The reports of the secretary and treasurer were read and adopted.

After the expenses were all paid, quite a sum was left in the treasury.

PLAIN SECTION AND FENCE SEPARATORS.

Mr. Crane then gave a talk on the plain section and fence, showing the different kinds of fence. He thought it was an improvement in getting the honey filled out to the edge of the section; thought the bees would store more honey because of freer communication. At the close of the season they were more apt to be sealed. Separators made with blocks were better than cleats. Another advantage was getting the outside sections filled with the rest. He had tried some of the 4x5 inch sections; was going to do so more extensively the coming season.

Mr. Leonard used the 4x5 section.

The present committee was ordered to report at the morning session what to do in regard to experimental work.

TRAVEL-STAINS.

Mr. Leonard then gave a talk on travel-stains. It was not all the dark honey that was made the first of the season. He had honey spoiled by the bees bringing in something to stop cracks with just as the season was closing. He did not know where it came from, but thought it was the same as the last run of sap—the honey that was gathered last. It was sometimes colored by the bees using old comb and capping, and sometimes by the bees taking honey out of the brood-nest and carrying it upstairs. It was not caused by the bees walking on it, as he had left the honey on until time to pack for winter, and it was nice and white.

SECOND DAY—MORNING SESSION.

The Committee on Nominations made the following report, which was adopted:

President—R. H. Holmes; Vice-Presidents—Addison County, J. E. Crane; Lamoille County, Geo. H. Terrill; Chittenden County, O. J. Lowrey; Orange County, P. W. Smith; and Rutland County, V. M. Forbes.

Secretary, M. F. Cram; and Treasurer, H. L. Leonard.

The Committee on Resolutions made the following report, which was adopted:

Resolved, That we as bee-keepers assembled thank our Heavenly Father for the prosperity of this Association, and trust that we may have many years of prosperity.

Resolved, That we express our thanks to John Higgins, the proprietor of the Addison House, for favors shown us at this meeting; also to the Rutland, Central Vermont, and Boston & Maine railroads for reduction in rates.

Resolved, That we express our thanks to Prof. Geo. H. Perkins, for his able address on the relation of other insects to bees; also to Prof. H. M. Seely, for interesting remarks.

W. H. BRISTOL, }
H. L. LEONARD, } *Com.*
G. W. FASSETT, }

THE HOUSE-APIARY.

Mr. Holmes then gave a description of his house-apiary. It is 51½ feet long, 12 feet wide, 7 feet and 1 inch high. In the north end is a place to drive in a team, and a large door from there into where the bees were. In the opposite end is a large door and window. On the sides are 30 windows 9x13, all hung on hinges. Each colony has an entrance 1½x8 inches. It is painted red, white and blue, each color taking in three colonies in each strip. The rafters project over two feet, so as to keep off the storm and sun. There is an alighting-board in front of each hive. The first stand for the bees is 15 inches from the floor, the upper one 4 feet. The frames running crosswise of the entrance make it easier to manipulate. There are several tables and benches thru the center of the building, the longest one 18 feet.

He moved the bees from out-of-doors into this house just after the honey-flow began, at night, in three different lots. The first time 31 colonies were carried in; they were the best ones. Some of the bees went back, and that strengthened those that were left. He carried in 19 the next time, leaving 11 of the poorest out-of-doors, which it strengthened immensely, making them about equal to the others. All were in good working order, and no fighting.

The whole cost of the building, aside from the work, was \$278.

Some of the advantages were, to be able to work when it rained; bees did not sting as badly as out-of-doors; he is not troubled by robbers, and could stay all night if it rained, and had done so several times. He had been awakened quite suddenly sometimes by a bee falling on him, striking sharp end first. He could take off honey much faster—had taken off 1,200 pounds after 5 o'clock p.m., and got the bees out before dark. Bees mix more or less, and some of the disadvantages were that he could not see quite

as well, especially when looking to see if the young queen had begun to lay. Out of 29 colonies 16 were queenless when looking to see if they had begun to lay. Some had superseded their queens, and then lost them. He would be obliged to have nuclei to supply the lost queens.

Mr. Leonard had a house-apiary, and lost half of the colonies each season, mostly in the fall. He thought they were too warm in February and March, causing the bees to breed too early.

MISCELLANEOUS DISCUSSION.

Then came general discussion on the different kinds of foundation. I think the Weed process came out ahead. Mr. Cook said Southern beeswax was harder than Northern.

How to get the most benefit from experimental work. The following committee were elected to confer with the board of control: O. J. Lowrey, M. F. Cram and J. E. Crane.

Would it be practical for Vermont bee-keepers to establish headquarters for the purchase of supplies? Mr. Fassett said with headquarters we might get supplies much cheaper, but he thought bee-keepers were not organized sufficiently to do so at the present time. Mr. Lowrey said he was in favor of drawing as close together as possible, in purchasing supplies, and thought we could save quite a percent by buying in carload lots.

It was voted that we recognize and fully appreciate the effort of the Vermont State Board of Agriculture in behalf of the bee-keeping industry of our State.

M. F. CRAM, *Sec.*

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, *Marengo, Ill.*

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Answering and Asking Questions.

In sending in a batch of questions, a correspondent has sent one that I have concluded to take out of its regular setting and answer separately. He says:

"DR. MILLER: Do you not get tired of answering questions about bees and bee-keeping? If any of the above questions are unimportant and not worthy of an answer, omit them; or, if you have answered them in the last five years refer me back, as I have the American Bee Journal covering that time.—SUBSCRIBER."

Seeing you've asked the question, I don't mind telling you that sometimes I do get tired. When a friend asks for some information that I happen to have, it's a real pleasure to give the information, but if one after another they keep asking questions all day long, it gets to be another thing. There's a difference, too, between answering some one sitting before me, of whom I can ask any explanations I like, and answering a question so worded that I can hardly tell what is really meant, but must answer somewhat in the dark. Sometimes questions are written in such penmanship that I may be obliged to puzzle a long time over some of the words. In some cases there's anxiety for fear the answers may be misleading. Then there are so many things that one doesn't know. If you want to get a realizing sense of your own ignorance as to matters apical, just try for a time answering questions for a bee-journal.

But there's a bright side to the case. I have very distinct remembrance of the time when so many questions were coming up constantly, and I would have given a good deal for a chance to receive replies as to things that might seem very simple to one of more experience. So it's no small pleasure to know that I'm helping to throw some light on the path I have already trod and which others are now treading. Of course I couldn't make so much of a business of answering questions without being paid for it, but if there were connected with it no thought of helping others it would be a somewhat irksome task. Sometimes, too, there comes a very pleasant word of recognition of help received from my answers, and a word of that kind is fully appreciated.

Once in a great while I receive a word of a different kind. Not long ago I had a letter from a man who was not entirely satisfied with an answer I gave, and in the course of his letter he said:

"Of course no one ever did ask the question. I was speaking about this 'question' matter with a bee-keeper the other day. He said: 'Do you really suppose any one ever asks such foolish questions as are found in the bee-papers?' You can guess what my reply was."

I smiled when I read that. It would probably trouble any one person to get up such a variety of questions. Neither is it necessary. The only trouble is to find room for all that come. The worst spell of questions in the history of this Journal occurred

somewhat more than a year ago. For some time questions rained down in such lively style that this department overflowed the page to which it was legitimately entitled, finally being satisfied with nothing less than two pages. Then came a flood, and beginning with the number for Feb. 28, smaller type was used to crowd as much as possible on two pages. In spite of that the work began to get behind, and only by continuing the fine print for 11 numbers was the work caught up with, and with the month of May matters returned to their normal course and the usual type was again used. No doubt, when the editor was struggling so hard to get all the matter in, he would have been somewhat amused at the suggestion that some one was making up questions; but the suggestion would be no more true at the present time.

The correspondent first quoted says I may refer to answers given any time in the past five years. That might do in his case, but would hardly do in general; for I may not know how long the inquirer has been taking the paper, and, moreover, if he should not be able to find in back numbers just what might fit his case, it isn't at all certain I should be able to do so. It is difficult, however, to keep down a discouraged feeling when a question comes that is fully explained in any good text-book on bee-keeping. There are plenty of questions left after one has become familiar with his text-book.

Side-Entrance Hives—Self-Hivers.

1. It is more convenient for me to use hives with side-entrances. Do the bees do as well in such hives as with end-entrances? If they do, why is the entrance almost always in the end of the hive?
2. In using the Pratt self-hiver, is it any practical hindrance to the workers while gathering honey? Is it practical?

OKLAHOMA TERRITORY.

ANSWERS.—1. In this country it is the almost universal custom to have the ends of the frame running toward the entrance, mainly because it is supposed to be better for ventilation, and because the bees can go more directly to any one of the frames. If it's a matter of serious inconvenience to you to have them thus, the difference is probably not sufficient to have them the other way.

2. I've had no experience. Perhaps some one else can tell.

Getting Swarms—Eggs in Queen-Cells.

1. I have 11 colonies of bees, and would like to get all the swarms I can by June 1. I have combs with sealed honey saved from last fall. How can I manage to get a good many swarms by that time?
2. How long after the first swarm will the second swarm issue? also, how long after the second swarm will the third issue?
3. How do the eggs get into queen-cells?

WISCONSIN.

ANSWERS.—1. Be sure that the bees have stores and to spare. See that there are no cracks or holes thru which heat can escape from the hives. When a swarm issues, some advise putting the swarm on the old stand and putting the old hive in the place of another strong colony, setting the latter in a new place. In a week or so a second swarm will issue, when the same old hive is to be put in place of another strong colony, and so on as long as swarms issue.

2. A second swarm is likely to issue about eight days after the prime swarm, but may be a little earlier or later.
3. Probably the queen lays them there.

Having Hives in Pairs in the Apiary.

You stated somewhere in some paper that you placed two hives as close to each other as you could and not have them touch, so I thought I would make a double hive stand. I made it much like the single hive-stand shown in my bee-supply catalog. The front and back pieces are long enough for two hives with a strip from front to rear between the hives 3 1/2 inches wide.

The strip is to keep down the grass between the hives and to help to place the hives true on the stand. Last year I used 55 stands of this description. Soon after putting the bees out of the cellar (March 7), I saw the bees from one colony crossing the strip between the hives and enter the other hive without opposition. I looked thru the visiting colony and found them queenless. In working among the bees I found four or five cases of the same kind, that is, queenless bees visiting the neighboring hive. These were all the queenless cases found in the spring.

I placed my bees in this yard in the spring of 1888 for the first time, having bought the place the fall before. There was not a tree in it until I planted them in the spring. The stands are 8 feet apart one way and 10 feet the other. I kept my bees all summer just about as you see them in the picture I send you, except in rare cases I used a shade-board. When the temperature was 90 degrees the bees began to cluster out, and in several cases the bees from both hives clustered together. This worried me for a time, but I have failed to notice any harm coming from it.

One end of the front of the stand is black and the other is white. The stand is kept level much easier than the single one, on account of its greater length. You will see how much clustering out was done, as this view was taken on a hot day in September.

I am of the opinion that young queens often entered the wrong hive, as I lost quite a number during the summer. I understand all the losses cannot be charged to having hives in pairs, yet that

and the regularity of the rows are somewhat to be blamed. I have left out one row of hives in the center which makes the central rows 16 feet apart in the rows. I am thinking of taking the central row out of each section of the yard, which will make five divisions instead of two, the hives removed making the fifth.

If you think my hives are far enough apart for safety to the queens and bees, will you kindly let me know, as they are much more easily cared for as they are.

It appeared to me that the central colonies were much weaker than those on the outside.

I want to thank you for kindly consenting to correct the statement in regard to granulation of honey. It is quite apparent that there is quite a difference in the character of honey gathered from like flowers in different localities.

NEBRASKA.

ANSWER.—Allow me to congratulate you in the first place on the neat appearance of your apiary. I think it never struck me before that an apiary is improved in looks by having the hives in pairs.

If I ever said that hives should be as close as possible without touching (and quite likely I did) I hereby take it back. I prefer to have them about four inches apart. Your 3 1/2 inches will do nicely.

The only grave charge, I think, that can be laid to having two hives on the same stand is the fact that under certain circumstances a queenless colony will unite with another. I think this will not happen in the summer if a colony becomes queenless in the ordinary course of affairs, as after swarming; but if you take away suddenly the queen, or if you take away all the brood and combs, there is danger sometimes of uniting. It may also happen in the spring when bees are first put out of the cellar. At such a time I'm not sure that anything better could happen, and it is so rarely that uniting occurs at any other time than in the spring that I have never considered it a serious matter.

I have never taken the precaution to have one end of the stand differ in color from the other, but it can do no harm, and may do some good.

The clustering together of two colonies side by side is a common thing when hanging out, but, like you, I've never seen any harm from it, and I don't believe any harm ever happens.

With regard to queens being lost on returning from the wedding-flight, I am very positive that putting the hives in pairs is not responsible for that, but, on the contrary, that there is much less danger of loss than if the same ground is occupied with the same hives placed singly at equal distances. Suppose on a treeless plain with no surrounding objects by which the bees can mark their location, you have a straight row of hives with a space of four feet between each two hives. A young queen can get into the wrong hive by going four feet out of her way. Now move each alternate hive so they stand in pairs, with eight feet between the pairs. A queen will go into the wrong hive only by going eight feet out of its way. That makes the chance of going wrong only half as much as it was when the hives were placed singly.

I think I hear some one say, "But the queen can get into the wrong hive by going out of her way only a few inches into the other hive of the pair." Listen. Bees don't make mistakes of that kind. Try this: In the spring close the entrance to a hive all but three inches at one end. When the bees are accustomed to that, so that each bee on returning to the hive goes straight to the part of the entrance that is open, change the place of entrance to the other end, closing up the end that has been open and leaving open three inches at the other end. If you never tried it before, you will be surprised to find what difficulty the bees will have in finding their entrance. I formerly kept two colonies in one 10-frame hive, a division-board in the middle, the entrances separated at the front six or eight inches. I have had many colonies in that way, and had many queens fertilized in them, and I think there was less mixing than with colonies in separate hives.

Suppose 30 colonies in a straight row in pairs, eight feet between the pairs. A worker or a young queen flies out from No. 15, the hives facing east and the numbers running south. If she makes any mistake at all, she is more likely to go into No. 13 or No. 17 than to go into No. 16, the other hive on the same stand. For she has marked the right hand hive, and there's no danger of her going into the left hand hive, but some danger that she may go into the right hand hive of an adjoining pair.

If there were no other advantage in having the hives in pairs than the one of having bees more easily find their own hives, I should consider that advantage very far outweighs the disadvantage of the few occasional cases in which a queenless colony may unite with its neighbor.

York's Honey Almanac is a neat little 32-page pamphlet especially gotten up with a view to create a demand for honey among should-be consumers. Aside from the Almanac pages, the forepart of the pamphlet was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample for a stamp; 25 copies for 40 cents; 50 for 60 cents; 100 for \$1.00; 250 for \$2.25; 500 for \$4.00. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

United States Bee-Keepers' Association.

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., E. Whitcomb; Vice-Pres., C. A. Hatch; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GEN'L MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

Place and Date of Next Meeting:

Philadelphia Pa., September 5, 6 and 7, 1899. Every bee-keeper is invited.

VOL. 39.

APRIL 27, 1899.

NO. 17.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

IF.

If we noticed little pleasures
As we notice little pains;
If we quite forget our losses
And remembered all our gains;
If we look for people's virtues
And their faults refused to see,
What a comfortable, happy,
Cheerful place this world would be.

—Farm Journal.

Following the Leaders.—Mr. F. L. Thompson has this sentence in the April Progressive Bee-Keeper:

"Sad experience has taught me that, all things considered, it is not the best policy to follow the leaders; but to cultivate an independent judgment in the matters which touch the pocket-book."

Well, that's a little tough on some of us beginners, if we can't take any advantage of the experience of those who have gone before, but must blaze our own way thru the forest, whenever the pocket-book is to be considered. As Mr. Thompson is one of the leaders, some will probably make a near application of his teaching by not following his present advice.

The Philadelphia Convention Rates.—It seems the railroad companies have already arranged the matter of rates for the Grand Army to Philadelphia in September. And that means the rates are also settled for the annual conven-

tion of the United States Bee-Keepers' Association. The following paragraphs are taken from the Chicago Record for April 14:

For the national encampment of the Grand Army of the Republic, to be held at Philadelphia Sept. 4 to 9, the Eastern roads yesterday agreed to make a rate of one fare for the round trip from Chicago and all points in the Central Passenger Association territory. The same rate will be made over all lines, standard and differential alike. It was also agreed that the Philadelphia rates should apply to New York. In addition, the lines running out of Philadelphia and Washington are arranging to make reduced rates for side trips to Richmond and Fredericksburg, and to the battlefields of Virginia.

Tickets will be placed on sale Sept. 1 to 4, inclusive, good for return up to Sept. 12. By depositing ticket with the joint agent of the lines at Philadelphia, and payment of a fee of 50 cents, the return limit can be extended up to Sept. 30. Liberal concessions in the way of stopovers have been made. Ordinary tickets will permit of one stopover in each direction in the territory east of Pittsburg and Buffalo. Upon payment of an additional \$2 another stopover in each direction will also be permitted.

The travel to the national encampment promises to be very heavy this year. The general public is expected to embrace the opportunity of visiting the seashore in September in large numbers. The roads are already "hustling" for business, and the gathering will probably be one of the best-attended in the history of the Grand Army.

We hope that the gathering of bee-keepers in Philadelphia will be one of the largest ever known in this country. Never, likely, will railroad rates be any lower than one fare for the round trip. It is yet over four months until the convention. Let all who can possibly do so make their plans to be there, all being well.

The Honey Prospects in Southern California.—Prof. Cook wrote us as follows April 10:

The rains have come, and we shall have a fine hay and grain crop. Will we have any honey? I think that remains to be seen. We have had far less rain than is usually supposed necessary to secure a honey crop. Yet we need more observation. It may be it has come at just the right time. Last year we had about the same rainfall as this, yet no hay crop. I find the flowers bunched this season. The black sage and other bloom are out two months earlier than usual. It may be that we shall have more and copious rains yet. In fact, a storm is now brewing. It may be that the rains will be so well timed that we shall have a honey crop even with less than the usual rain. Several of our best apiarists are moving their bees to the alfalfa regions of central California. A. J. Cook.

Getting Farmers to Keep Bees.—Occasionally there arises some one who in no uncertain words deprecates the idea of getting all the farmers and fruit-growers to keep bees. But Mr. J. H. Tichenor, of Crawford Co., Wis., believes in the opposite view, and expresses himself as follows on the subject, giving reasons for the faith that he holds:

"What shall it profit a man if he gain the whole world and lose his own soul?" This is, in my opinion, just what we as bee-keepers are doing when we try to keep our farmer brethren out of the bee-business. Let me give you some reasons why it will pay us to induce our farmer neighbors to keep a few bees:

1st. Farmers are learning that they must spray their fruit-trees, and in so doing are slaughtering bees by the wholesale. Now, if every other farmer owned one colony each, just a hint to them that they might kill all of *their* bees would be sufficient to prevent this evil.

2nd. It would be no trouble to get them to subscribe for our modern bee-literature, and thus learn that it requires some effort on our part to produce a paying crop of first-class honey. And they would appreciate our efforts to produce *good* honey. No teacher is as good as experience.

3rd. They would learn to *like* honey, and so would consume more of it, thus advancing the price of a first-class article.

4th. The final outcome will be (I speak somewhat from experience) not more than one out of ten will ever make a

success of bee-keeping (thus no more honey produced), but each one, having acquired a taste for honey, will never again be found without honey on his table (thus much more consumed). And they will all say, "I see now that you people earn your money, and that dollars don't roll uphill to you without effort on your part, as I once believed they did."

Now, I honestly think that this is a fair probability of results; and having cleared my conscience of what seemed to me a duty, I submit the foregoing.

J. H. TICHENOR.

We think Mr. Tichenor has advanced several good reasons why farmers should more generally keep bees. His views will doubtless help to strengthen Rev. E. T. Abbott in his belief along this line, as he (Mr. A.) has several times threatened to start a paper to be called "Farm Bee-Keeping." We very much doubt if such a paper would pay, tho we believe thoroly in the idea that it would be no detriment to anybody if each farmer would keep about five colonies of bees—at least enough to produce honey for his own home.

Barrel an Unsatisfactory Honey-Package.—A bee-keeper and honey-dealer to whom we have sold quite a good deal of honey in barrels the past few months, wrote us as follows lately:

"A barrel is a very unsatisfactory honey-package for the man that handles it in the last instance. Nineteen times out of 20 the barrel must be taken apart to get the honey out."

We have often wisht that those who put up their honey in barrels could be compelled to buy and handle such honey for awhile. After they had a little experience with the stuff leaking out, and a number of pounds soaking into the wood—all the loss, of course, to come out of their own pockets—we believe they would be done with putting honey into barrels or wood of any kind. Tin is the thing for a honey-package. In some instances a half-cent a pound more can be secured for honey in tin.

Mr. J. L. Hubbard, whose picture appears on the first page of this issue, until a few years ago lived in New Hampshire. He wrote us as follows some time since:

MY DEAR MR. YORK:—I received the first number of the American Bee Journal soon after its publication in 1861, and think I have had every number printed since then. They have been read and studied with much pleasure, and, I hope, profit. It has ever been a champion of the right and progressive in its ideas. At first it was supposed by some that the whole subject would soon be gone over, and that there would then be but little use for a bee-journal, but the subject seems to have been continually opening in new directions, and grows more interesting.

Besides teaching new ideas in bee-keeping a bee-journal is very useful to keep one posted in regard to the business in all parts of our country and the world.

In the earlier days of the Bee Journal my name was sometimes found in the reading and advertising columns, but of late years I have been doing but little in the bee-line, and am now sojourning among the mountains of western North Carolina.

The American Bee Journal has not lost vigor by age, but, if possible, grows more reliable. May it live long and prosper.

J. L. HUBBARD.

Henderson Co., N. C.

An Illinois Pure Food Bill was past at the late session of the legislature. It was introduced by Senator Dunlap—one of the best men in the whole State. From an editorial in the Chicago Record of April 14, we take these paragraphs:

This measure is one of the important ones to be enacted at this session of the legislature. Illinois has been backward in pure-food legislation. The passage of this Bill means that a start at least is to be made in the direction of State supervision of food products offered for sale. Time will show what changes are necessary for the perfection of the law. It was not intended to be very far-reaching in its effect at the outset, but was designed by its framer, Senator Dunlap, to serve rather as the beginning-

point for other pure-food legislation. It creates the machinery for food inspection, with the intention that the duties of the inspection officials will be gradually enlarged.

The Bill creates the office of State food commissioner, to be filled by appointment of the governor. The salary is \$2,500 a year. The commissioner, with the consent of the governor, may appoint two assistant commissioners at a salary of \$1,800 a year each, one of whom must be an expert in dairy matters, and the other a practical and analytical chemist. The commissioner is also authorized to appoint necessary inspectors, not exceeding six in number, the compensation of the inspectors to be \$3 a day and expenses. It is made the duty of the commissioner to enforce laws now existing, or that may hereafter be enacted regarding the production, manufacture and sale of dairy products, or the adulteration of any article of food. The terms "food" and "adulteration" are defined, and the sale of articles adulterated within the meaning of the Act is forbidden under penalty. The Bill also makes regulations concerning vinegar, candy, fruits and vegetables, jellies and jams, extracts and chocolates and cocoas.

In order to give dealers time to prepare for the operation of the Act, the enforcement of penalties under it is suspended until July 1, 1900.

Our only regret is that the new law doesn't go into effect July 1, 1899, instead of a year later. But it is really encouraging to feel that we have such a law, and there is hope that in time we shall be able to make the adulteration road a hard one to travel.

Now, if a food commissioner who has more than a cotton string for a backbone is appointed, there will be just cause for hope that in a few years the consuming public will be reasonably sure of getting just what they pay for in the line of things to eat.

MR. E. L. CARRINGTON, of Florida, desired us to announce that he will not offer queens and bees for sale this year, as all his bees are dead or dying.

"TWO WORLDS" is the name of the \$50 prize story begun in the Progressive Bee-Keeper for April. It was written by Mrs. J. M. Null. There were 17 contestants for the prize.

THE FARM JOURNAL is cream, not skim-milk, and just the paper for the man who keeps cows. We give it for the balance of 1899, and all of 1900, 1901, 1902 and 1903, nearly five years to every subscriber who accepts the offer on page 254. This is a short time offer, as we have only a small number of Farm Journal subscriptions on the terms offered.

MESSRS. F. L. MURRAY AND F. P. WHITE, of Lafayette Co., Wis., called on us last week. Mr. Murray is the secretary of the Southwestern Wisconsin Bee-Keepers' Association. Mr. White's bees have wintered very well, but Mr. Murray lost quite a number of colonies. The latter has two apiaries. We hope soon to show pictures of the apiaries of both Mr. White and Mr. Murray.

SOMNAMBULIST, in the Progressive Bee-Keeper for April, has these congratulatory words to offer in reference to our new department, called "The Afterthought," in charge of that cogitating individual:

"Permit us to congratulate you, Friend York, on your new department, for all the Journal readers extend to it a most hearty welcome. But as to 'unreliable glasses' being strictly appropriate—well, one cannot help seeing a clash of arms between that word 'unreliable' and the matter following."

"Sommy" and "Cogy" ought to get acquainted. They'd make a fine team.

Consumption of Stores in Severe and Mild Winters.

In the severe winter of 1894-95, amount of stores consumed per colony from Nov. 1 to March 1 was 7.5 pounds, and 13.4 during the same time in the mild winter of 1897-98.

Fruit-Bloom Honey, Mr. Robertson thinks, is a bad thing to get mixt with light honey. He believes raspberry is as bad as fruit-bloom, and, altho not very dark, raspberry is about as poor flavored honey as there is.—Canadian Bee Journal.

Large Hives for Outdoor Wintering. In an apiary of 80 colonies, 50 in Quinby 11-frame hives and 30 in Langstroth 10-frame, only one in 25 died the past winter in the large hives, while one in three died in the Langstroth hives.—Chas. Dadant, in *Gleanings*.

Crimson Clover has for the fourth or fifth winter wintered beautifully in Medina Co., Ohio. Mr. Root sowed some last August in wheat that grew so rank it fell down. It looks fine this spring, except in some spots bare of wheat. It is of some consequence to learn in what localities it is, and is not worth while for bee-keepers to sow crimson clover.

At what Stage Should Honey be Extracted? was a question discusst at the "Meeting of the senate of Canadian bee-keepers." Mr. Holtermann thought it should be left till the honey has a glossy, shiny look in the cell. Mr. Robinson thought the longer left on the hive the better, so long as the weather is warm and dry. Mr. Shaver had had sealed honey become thinner when left on the hive, perhaps on account of rainy weather.—Canadian Bee Journal.

A Commission Man on Tall Sections.—H. Segelken, of Hildreth Bros. & Segelken, New York, tells something of the New York market in *Gleanings*, and thinks the 4½ x 4¼ sections have had their day. He thinks the tall sections will drive them out in time, just as the one-pound section drove out the two-pound section. The size preferred is 4x5 x1¾, without bee-ways, with a leaning toward something still narrower. The demand is for sections of 12 or 13 ounces. He favors selling honey, not by weight, but by the piece, and by the crate. "The demand for honey in paper boxes has fallen off somewhat for the past two seasons, and unglast has been in better demand than heretofore.

Strong Colonies for Results can hardly be repeated too often. In the *Progressive* bee-keeper R. C. Aikin says:

"Hold your forces together if you want surplus. Better take a few bees from each strong colony, and make nuclei, and ask nothing more of these, but to get in winter stores and make colonies for winter, and see that the parent colony gets you surplus."

Doolittle endorses this, but says if little increase is needed it is better to make no nuclei, but make strong colonies at once, by using a big funnel and nucleus-box and going from colony to colony till 7 to 10 pounds of bees are obtained, then giving a queen. This keeps down swarming, and yet keeps all at work in the supers.

Colorado Grading of Honey. F. L. Thompson reports in the *Bee-Keepers' Review* the system of grading comb honey adopted by the Colorado Association, and a very fine half-tone picture shows six sections of each of the two grades. The grades are as follows:

"No. 1. Sections to be well filled; honey and comb white; comb not to project beyond wood; wood to be well cleaned; sections to weigh not less than 21 pounds net, per case of 24 sections; but cases in lots must average 22 pounds net. (That is, if a few cases in a lot weighed 21 pounds each, that would not prevent the whole lot from being first grade honey, provided the average of the whole lot was 22 pounds.)

"No. 2. Includes all amber honey, and all white honey

not included in No. 1; to be fairly well sealed, and not weigh less than 18 pounds net per case of 24 sections.

"Culls.—All cull honey shall be sold in the home market."

One might ask why cull honey should be inflicted on the home market if not fit for shipping. The reason given is a very commendable one: On account of the use that may be made of them to be cut up into strips to have glucose poured over them. Cull honey is not defined.

One of the hardest things for an outsider to see thru is that matter of 21 and 22 pounds. If a lot averages 22 pounds per case, and a 21-pound case is added, then a 23-pound case must be added to balance it. When it comes to selling out by the single case to the grocer, each 21-pound case is first-class, then why would not a whole lot of the same kind grade just as high? But it may be that demands of grocers in the same market may vary.

It is a very much easier thing to find fault with a system of grading than to evolve a faultless one.

Increase by Nuclei.—Remove or cage the queen. Ten days later take two frames of brood with adhering bees, put in an empty hive at one side, using a full comb of honey as a division-board. Stuff the entrance with green moss, grass, or leaves, packing it in very tight, so not a bee can get out. See that at least one good queen-cell is in each nucleus. In two to five days the bees will gnaw a way out, and not a bee will go back to the old place. Each strong colony should make four or five good divisions, that will become good colonies in 40 or 50 days. Enlarge the entrance when the bees gnaw out. The old queen, if good, may be freed in the hive on the old stand without fastening in the nucleus.—W. W. Somerford, in *Gleanings*.

Parthenogenesis—as in the case of perfect male bees being produced from unfertilized eggs—seems a thing somewhat difficult of belief to some people. Stranger things, however, occur among other classes. The aphid, or common plant-louse, is only to be seen in the perfect winged form in the fall. After mating, the female lays eggs in the recesses of plants, these eggs hatching the next spring, but producing only wingless lice. Without mating, these wingless lice bring forth other wingless females, not hatch from eggs, but born alive, and these in their turn bring forth others, so that they often extend to nine or ten successive generations, until the last brood brings forth males and females with wings, and from these come the fertilized eggs in readiness for the following spring.

"Face the Hives South," says Sonnambulist, in the *Progressive Bee-Keeper*, endorsing Doolittle, "giving them the advantage of more frequent cleansing flights during a severe winter, and lengthening not only the season, but the separate days which constitute the season;" advising that the apiary be placed where the general lay of the whole country is to the south, as the southern slopes warm up sooner and blossoms appear there in advance. That raises the question whether Sonny, who always dreams so brightly, must not have been in an abnormal condition when penning that. Wouldn't an apiary with a northern slope get those southern-slope flowers all right? Or is the slope to be continuous as far as the bee flies? As to the general question of north or south facing, or facing some other direction, Cogitator probably has it about right—"whole thing a matter of climate."

Sections Without Separators. W. B. Ranson reports in *Gleanings* that without separators he secures sections with only 21 in a thousand bulged. His chief dependence is upon very strong colonies, with hives carefully leveled. He encourages early brood-rearing, and, when the colony swarms, removes the queen and lets the swarm return. In eight or ten days they swarm with the virgin queen. He removes the old hive and puts the new in its place with perforated zinc at the entrance, running the swarm into the new hive, and allowing only the best young queen to go in. On the hive is put an excluder, over this a super of sections, with starters, and on this the super of unfinished sections from the parent. Then the bees from the old hive are brushed into the new, the old hive closed with wire-cloth, put in a comfortable place, and in 24 or 48 hours the bees again brushed out into the new hive, and the third day the excluder removed from the entrance. That makes a powerful colony with no danger of swarming again, and work goes on so strongly in the sections that no separators are needed.

Root's Column
